## New Farms Too Small To Cash In On Corn-Hog Benefits

Almost no Illinois farm is too small to get some of the benefits of the government's corn and hog adjustment program, and every farmer who does take part will stand with his neighbors in helping to restore a fair exchange value for these two farm products, it is pointed out by the extension service of the College of Agriculture, University of Illinois. Any farmer who can comply with one of four different combinations of corn and hog production can get a contract and receive the benefit payments.

Every corn and hog farmer in the state will have a chance to learn the details of the plan in community meetings which county farm advisers and the extension service of the College of Agriculture, University of Illinois will hold throughout the state.

Permission for a farmer to sign the contract for only one commodity is made possible through a special ruling of the Agricultural Adjustment Administration.

If in 1932 and 1933 a farmer grew an average of 10 or more acres of corn and marketed four or more litters of pigs, he may sign the adjustment contract to reduce his corn acreage in 1934 at least 20 per cent and his hog production 25 per cent. He thereby becomes eligible for benefit payments on both corn and hogs. He must reduce his production of both to be eligible for either or both payments.

If the farmer, in the two-year base period, grew an average of more than 10 acres of corn but marketed less than three litters of hogs, he can sign up for the corn payments, but will not be eligible for any hog benefits. In 1934, however, he must not increase his hog production.

If any \_\_\_\_\_ county farmer grew less than 10 acres of corn as an average for the two years, 1932-1933, exclusive of corn for silage, but marketed three or more litters of hogs, he may sign up for the benefit payments on hogs. He must not, in this case, increase his corn acreage in 1934.

If the farmer grew an average of 10 or more acres of corn in 1932 and 1933 and only three litters of pigs, he has a choice between two possibilities. He may reduce his corn acreage by 20 per cent and agree to produce not more than three litters, thereby becoming eligible for corn benefits but will not receive payments on hogs. If he desires, he may agree to reduce his corn production as specified and his hog production to two litters, thereby becoming eligible for payments on both his hogs and corn.

Any farmer who grew less than 10 acres of corn and marketed less than three litters of pigs during the base period is not eligible to sign a contract.

Journal of Daily Issues Will Center on Home Week

Inflation, taxation and all the other leading issues of the times will be covered in eight general sessions which will climax the program of the thirty-sixth annual Farm and Home Week, January 18 to 19, at the College of Agriculture, University of Illinois, it is announced by Dean F. W. Hunter.

As a foundation for the eight general sessions and special short courses, all keyed to the recovery and adjustment needs of farmers and homemakers, will run throughout the week. Special entertainment features, meetings of a number of the state's rural organizations and other features will be combined with this instruction to make the week a "new start" for the hundreds of farmers and homemakers who annually attend the event.

A "planned" agriculture for the future is expected to be touched upon in the first general session of the week, Monday afternoon, January 18, when DeWitt C. Wing, of the Agricultural Adjustment Administration and former farm paper editor in Illinois, comes back from Washington, D. C., to speak on, "Farming of Facts and Fables."

Needed reforms to reduce the cost of local and county government, a problem close to the hearts of farm people, will be discussed in the Tuesday morning general session, January 18, by Dr. M. H. Hurst, University of Illinois professor of economics.

Inflation will get its hearing at the Tuesday afternoon session when Dr. Max J. Wasserman, University of Illinois assistant professor of economics, speaks on, "The Experience of France With Inflation."

The Wednesday morning session, January 19, will bring one of the highpoints of the week for many farmers when Wood Netherland, general agent of the Farm Credit Administration, St. Louis, Mo., speaks on, "The Farm Credit Administration and Illinois Agriculture."

"Buying Standards for Consumers" will be discussed Wednesday afternoon by Miss Ruth O'Frier, chief of the division of textiles and clothing in the bureau of home economics, U. S. Department of Agriculture, Washington, D. C. "European Trade Barriers in Relation to American Agriculture," Thursday morning by Dr. C. G. Stewart, chief in farm economics, U. I. College of Agriculture, and "The Outlook for Farming From the Farm Point of View," Thursday afternoon by Liberty Hyde Bailey, author and horticulturist, Ithaca, N. Y.

Clare E. Wickard, assistant chief of the AAA compliance section, is scheduled to close the Farm and Home Week program Friday morning, January 19, with a report on progress in the corn-hog campaign.

-M-

Three Major Items Figure In Costs of Producing Eggs

The three big items in the cost of producing the 12 billion dollars worth or more of eggs that Illinois farmers sell every year are feed, depreciation, which includes mortality, and labor, according to records which 20 poultrymen kept during the past year in cooperation with the extension service of the College of Agriculture, University of Illinois.

Any flock owner who cuts down on these items therefore will be going a long way toward getting a wider margin of net return out of the cash that he receives for his eggs, it is pointed out by H. H. Alp, poultry extension specialist of the college.

"Probably the best opportunity to reduce feed cost is to improve the average egg production of each hen in the flock, as the good layers eat but little more feed than the mediocre layers. Too many flocks carry about 20 per cent defaulters--hens that start laying and then quit--and it is this class of birds which runs up the feed cost of a dozen eggs.

-M-

Illinois Dairymen Get Example For State Fair's Plan

Illinois' most progressive dairymen are not waiting for a government plan to kill off disease-bearing inferior stock. They are carrying out a relief project to help bolster their incomes. Already these dairymen are members of dairy herd improvement associations organized by the Extension Service of the College of Agriculture, University of Illinois and proceeding with a cow culling plan at a rate which if followed by all dairymen would mean the disposal of 2 to 3% of the poorer cows in the state within a year.

In this respect the cow culling which the Illinois dairymen already are practicing is quite similar to recent proposals made to the federal administration for adjustments in the dairy industry.

Figures available by J. G. Calkins, assistant in dairy extension at the agricultural college, show that in the year ending last year 13 per cent of the 1,000,000 cow enrollment in the 27 dairy herd improvement associations of the state were culled, while in November, 1934, 12 per cent were culled in the producer's block.

"At this rate 24 per cent of the cows in dairy herd improvement associations will be culled this year," Calkins says. "If this rate in the state went into effect, the number of cows of the dairy type in the stables, it would mean that about the same number of cows would be disposed of."

Illinois dairymen get approximately 10 per cent of their gross income from the sale of dairy products, and the policy of heavier and better cows has been advocated by the extension service of the agricultural college as a means whereby the margin of net return on this business could be protected.

To illustrate how dairy returns may be improved by better handling of heavier and better cows, Cash, chief of the records of a branch of the Hancock County Dairy Herd Management Association, for the recent month of June first month was farmer owned cows, and the records indicated that about 60 per cent of them did not produce enough milk for their feed. In the second half of the cow culling following month he 10 returned \$1,400 more net proceeds than the 10 cows that were culled. Likewise the 10 cows that were culled, he believed he collected markets of 4,000 pounds of milk a month.

17

AAA Problem Of Land Handling In At Seed Grain Show

Between 1,000,000 and 2,000,000 acres of Illinois land may be contracted to the government as a result of the AAA programs on wheat and corn and hogs. By cash to handle this land, together with other soil and crop management problems in relation to the agricultural adjustment program, are expected to bring a record number of farmers here for the soils and crops short course of the thirty-sixth annual Farm and Home Week, January 18 to 19, at the College of Agriculture, University of Illinois.

Farmers of the state have been adjusting their cropping programs for years, as shown by the fact that the acreage of legumes has been steadily increasing and the acreage of wheat and corn has been declining, it was pointed out by Dr. W. D. Burdette, head of the college agronomy department. However, the AAA program will speed up the rate of adjustment, and the Farm and Home Week program will be designed to help farmers meet the new pace, it was explained.

The soils and crops program, itself, will not get under way until after the annual Illinois Seed Grain and Utility Corn Show has been opened on Monday afternoon, January 18, and farmers have had a chance to inspect the samples and exhibits.

Farm Credit Aids Will Be Outlined At Farm-Home Week

Prominence of Illinois in current farm credit activities assures farmers that they will get ample help in ironing out their financial troubles when they attend the thirty-sixth annual Farm and Home Week, January 15 to 19, at the College of Agriculture, University of Illinois, it is pointed out by those in charge of the program.

Wool Netherland, general agent of the Farm Credit Administration, St. Louis, will be the headliner and will appear on the Wednesday morning general session program at 11 o'clock to speak on, "The Farm Credit Administration and Illinois Agriculture." Herbert W. Mumford, dean of the U. I. College of Agriculture, is a member of the board of directors of the Farm Credit Administration in the St. Louis area.

Prof. H. C. M. Case, chief of the college's division of farm management, who is now on leave as assistant to Dr. W. I. Myers, governor of the Farm Credit Administration in Washington, will return to discuss farm debt conciliation and re-financing. He is in charge of this work for the FCA.

This event will come Wednesday morning, January 17, at 9 a.m., as the opening number in the special course on farm credit problems. This farm credit course is one of 26 different ones being offered throughout the week as a means of helping farmers and homemakers work out their own recovery and adjustment programs.

Following Prof. Case's opening of the farm credit course, C. E. Hopkins, a director of the Farm Credit Administration, St. Louis, Mo., will tell what is happening to farm mortgage indebtedness in Illinois.

Illinois is now the first state in the Union to be completely organized for production credit purposes, and this phase of farm credit work is to have the whole of Wednesday afternoon program, January 17, devoted to it. Leading off the discussion will be Dr. E. J. Norton, assistant chief in agricultural economics at the college, who is now on leave doing special production credit organization work for the Farm Credit Administration. He will discuss production credit problems and procedures.

Potential use of cooperative banks by Illinois associations will be the subject of a round-table discussion which will be led by J. B. Cosgrove, acting president of the St. Louis Bank for Cooperatives, St. Louis, Mo. Speakers will include L. E. Merchant, manager of the Illinois Farm Supply Company, Chicago; C. H. James, Southern Illinois Seed Growers' Exchange, Flora, and Harrison Fahrnkopf, of the Illinois Grain Corporation, Chicago.

-M-

FVA Funds May Give Farm Communities A Meeting Place

Many rural communities of Illinois now have a chance to overcome one of their worst drawbacks--the lack of a community meeting place--by getting through a CWA or FVA project for the building of a community center, it is pointed out by E. E. Lindstrom, associate in rural sociology at the College of Agriculture, University of Illinois. More than 400 community groups have been organized throughout the state during recent years by the extension service of the agricultural college, and there are scores of other groups that have been in existence for years, he said. Lack of a good community meeting place where such groups can have their social and educational programs is one of the real barriers in rural advancement, he believes. For the first time an opportunity for having such a building is opened up to rural communities through the provisions of the FVA and the CWA. Any rural community can submit a project for community building improvement, community building construction or park improvement.

-M-

Balanced Dairy Rations Mean \$12,000,000 In Relief

If Illinois farmers made just one New Year's resolution--to feed their milk cows balanced rations this year--they would get at least \$12,000,000 worth of "relief" in feed bills, says J. G. Cash, assistant in dairy extension at the College of Agriculture, University of Illinois.

All they would have to do in order to pocket this cash would be to save \$1 a month a cow in the feeding of the 1,111,000 cows now on farms of the state.

This is an extremely conservative goal, Cash believes, because it is based upon accurate records taken on cows owned by progressive dairymen who are members of dairy herd improvement associations organized by the extension service of the agricultural college. Considering all dairy herds of the state, it is likely that a change from the almost universal use of unbalanced rations to balanced, might save much more than the \$12,000,000 total in 12 months.

That this is not an unreasonable possibility is shown by actual records from dairy herd improvement association herds. In Knox county, for instance, a new member of a herd improvement association was feeding an unbalanced ration of farm grains to his 14 cows. He revised his feeding methods, as suggested by the cowtester, and reduced his feed cost \$15.06 in one month without lowering his production level.

"One month a new member of the Kankakee association fed 2,520 pounds of an unbalanced ration. The next month he fed 2,511 pounds of a balanced ration with the result that his feed bill was \$7.40 less than the previous month. Here, again, there was no change in the cows' milk production.

"By changing his ration from corn, oats and a high-priced protein supplement to corn, oats, bran and cottonseed meal, a Christian county dairyman reduced the price of his ration 11 cents a hundredweight without affecting production. This will make a saving of approximately \$36 for the year on his herd of 18 cows."

-M-

Destructive Pest Of Fruit Trees Is In For "Big Year"

San Jose scale--the little insect that plays havoc with promising peach and apple crops--had a rather prosperous 1933, and may have a "happier and more prosperous New Year," warns S. C. Chandler, assistant entomologist of the Illinois Natural History Survey, in a statement issued to the extension service of the College of Agriculture, University of Illinois.

"That is," says Chandler, "there is likely to be a large increase in San Jose scale infestation throughout Illinois orchards, unless fruit growers spray their trees this winter and early spring with oil emulsion or miscible oil to check the threatened 'prosperity' of the insect."

The annual San Jose scale survey completed a short time ago showed a very marked increase in this insect over the late fall of 1932. One hundred thirty-eight peach and apple orchards located in the southern fruit sections of the state showed 27 per cent of them to have a moderate to severe infestation in at least some part of the orchard. A year ago only 6 per cent of the surveyed orchards were in this condition.

Two reasons account for this situation--lack of spraying and a favorable season. In 1932 many growers took advantage of the small amount of scale and as an economy measure omitted the dormant spray. Then too, the warm weather of late October and the first half of November this past fall allowed an extra brood to develop, which if not checked by a dormant spray this winter will result in dead and dying limbs in 1934.

The standard Illinois recommendation for scale control is either oil emulsion used at the rate of 3 gallons to each 100 gallons of spray or miscible oil used at the manufacturer's recommendation.

## Five Thousand "Farm" Leaders Ready for Corn-Hog Sign-Up

Approximately 5,000 "farm leaders" have received their instructions and are all set to lead the Illinois corn-hog adjustment drive to its climax, when the state-wide sign-up days are announced, says an extension service of the College of Agriculture, University of Illinois. For six weeks a series of educational conferences held throughout the state.

These "farm" leaders represent practically every rural community in Illinois, and during the last 10 days they received special training in schools conducted by farm advisers and members of the college extension staff. Instructions dealt with the contract that will unite farmers of the corn belt in a movement to raise the market prices of corn and hogs to a fair exchange value with the things rural people buy. To attain this price improvement, the producers agree to cut their 1934 corn acreage at least 5 per cent and their hog production 25 per cent below their 1932-1933 average, and in return will receive a proportionate share of the nearly \$350,000,000 in benefit payments to be made by the Agricultural Adjustment Administration to cooperating farmers.

Within the next ten days the 5,000 "farm leaders" will aid farmers in their respective communities to fill in the work sheets, prepare maps of their farms, gather supporting evidence regarding corn and hog sales during the past two years and answer questions that arise in the application of the contract to individual farms.

When the 1,000 community sign-up stations are established at the peak of the campaign, these especially-trained leaders will man the booths and help the thousands of cooperating farmers fill in the final contract and other documents.

Interest in the corn-hog adjustment program is said to be running high in Illinois and a large percentage of the state's 210,000 farmers is expected to take part. It is estimated that at least two days will be required for the 5,000 leaders to receive and compile the signed contracts.

One of the first contract signers in the state has been reported from Christian county by Farm Adviser T. H. Brock. Without waiting for the sign-up days, this farmer collected all the necessary information and evidence on his corn and hog production and came to Farm Adviser Brock's office of his own accord to complete the sign-up.

-M-

## McDonough County Wins Two Major Corn Titles Of Year

Clarence Watson, of Macomb, McDonough county, became the new "corn king" of Illinois when his ten-ear sample of yellow utility corn won the grand sweepstakes in the annual Illinois Seed Grain and Utility Corn Show held in connection with the thirty-sixth annual Farm and Home Week at the College of Agriculture, University of Illinois. His sample scored 83.7 points out of a possible 100. Frank Brown, of Ardo, won the sweepstakes prize on ten-ear samples in the junior classes and thereby became the "corn prince" of the state. H. B. Smith, Bardolph, McDonough county won the annual Illinois Ten-Acre Corn Growing Contest when he scored a total of 89.97 points out of a possible 100 on yield, costs and quality of grain.

-M-

Planned Marketing Is Necessary To Get Most From AAA

Illinois farmers who sign the corn-hog adjustment contracts must also give attention to how and where they sell their hogs, if they hope to get the greatest benefits from the AAA program, says R. C. Ashby, associate chief of livestock marketing of the College of Agriculture, University of Illinois.

"Granting that there is a surplus of hogs, will not a reduction in supplies result in a surplus of packing plants or plant capacities, and in a surplus of distributive organizations and personnel?" asks Prof. Ashby. "As the volume of slaughter decreases, packers must accept a lower margin per hog or cut operating costs, which is probably difficult under NRA provisions, or widen the margin between the price of hogs and the wholesale price of hog products. The packers also have the alternate of leaving hog margins unchanged but charging a larger portion of overhead expense against beef cattle and lamb operations.

"Likewise, assuming reduced hog supplies, it may be expected that competition between packers for both quality and quantity will be stimulated. However, to get the full benefit from such transition, the producers must adopt and support sound policies of marketing." In this connection Prof. Ashby explains that such a marketing policy might well include:

- 1.--Elimination of all ineffective hog salesmen and sales agencies both cooperatively and privately operated.
- 2.--Better coordination of sales objectives by sales agencies on each market. Twice in 1933, sales agencies at Chicago demonstrated that a sales program can receive the united market support.
- 3.--Coordination of markets in support of a sound sales program.
- 4.--Patronize only those local markets which demonstrate ability to sell hogs on a parity with competing terminals--quality and price considered--and which return to stockmen their full share of the possible savings.

"Individual producers cannot achieve such a program," says this market specialist, "but groups of stockmen can when enough of them demand it. Planned marketing is the logical sequel of planned production."

-M-

Even Old Dairy Bulls Get "New Deal" On Many Farms

Old dairy bulls in Illinois are not headed for the last round-up" but are in line for a "new deal" as a result of a higher regard held for them by dairymen of the state, says C. B. Rhode, member of the dairy department of the College of Agriculture, University of Illinois.

Many Illinois dairymen plan to reduce the size of their herds, explains Prof. Rhode, and to work with fewer but better cows. Since the quality of the cows, and not the number, is being emphasized, these men naturally turned their attention to the selection of dairy bulls that will sire efficient producing daughters. Many farmers have had the experience of butchering the best bull they ever owned before his daughters came into production.

A program launched by the extension service of the college, calling for a careful selection of young sires, keeping the good bulls until their daughters come into production, and securing production records through dairy herd improvement associations has been responsible for retaining many good old bulls. Such sires of caliber fit into the national farm adjustment programs planned to give greater net returns on reduced volume and expense, says this dairy authority.

## Alleged Fraud on Corn-Hog Tax in Illinois

Illinois corn and hog producers are accused of additional bookkeeping fraud for the \$4,000,000 in benefits granted them by the AAA. It is the conviction of legislative and judicial grand juries in several counties of the College of Agriculture, University of Illinois.

The grand jury, which met at the University of Illinois, charged several counties with holding back from the AAA the distribution of corn and hog tax benefits. It is alleged that the AAA has been defrauded of \$4,000,000 in benefits. It is alleged that the AAA has been defrauded of \$4,000,000 in benefits. It is alleged that the AAA has been defrauded of \$4,000,000 in benefits.

The grand jury also charged several counties with fraudulently obtaining benefits. The grand jury also charged several counties with fraudulently obtaining benefits.

Wheat Checks To Illinois Growers Exceed \$1,135,000

Buying power of Illinois farmers has been increased by \$1,135,891 within recent weeks as a result of participation in the wheat production adjustment program last fall, according to figures compiled by the extension service of the College of Agriculture, University of Illinois.

This amount is represented in checks mailed to 41,894 farmers in 67 counties of the state by the Agricultural Adjustment Administration, Washington, D. C., as the first benefit payment made to those who agreed to reduce their 1934 wheat acreage by 15 per cent as compared to their average acreage during the three base years, 1930-1932. Checks to wheat cooperators in the other 35 Illinois counties are being sent out from the AAA headquarters as quickly as the contracts can be checked and accepted by the Secretary of Agriculture.

This first payment is at the rate of 20 cents a bushel on the allotment each farmer received, and the second payment of 8 cents a bushel, minus the pro-rata cost of administering the plan in each county, will be made after the spring planting season. Illinois farmers will receive approximately \$1,612,000 in benefit payments on their 1934 wheat crop.

With a total of \$29,170 in 3,117 checks, St. Clair county leads in total payments made in Illinois so far. Mason county ranks second, at this time, with 1,100 checks to farmers totalling \$76,074. Randolph county has received \$61,932 in 1,251 checks, Cass \$52,570 in 706 checks, Menard \$39,638 in 502 checks, Washington \$37,267 in 886 checks, Scott \$32,809 in 589 checks, Pike \$31,524 in 390 checks, Macoupin \$23,592 in 669 checks and Jackson county \$22,476 in 481 checks.

More than 2,000,000 acres will be taken out of wheat production in the United States in 1934 as a result of the wheat production adjustment program. The purpose of the project is to reduce domestic production in line with actual consumption and exports, which in turn is designed to bring wheat prices up to a fair exchange value with the things farm people must buy.

-M-

Assured Sale Of Crops Is Essential On Small Farms

Thousands of city dwellers who are considering the possibilities of moving onto a small farm with the hope of improving the family income should bear in mind that such farms are likely to be disappointing unless careful plans are made for the production and sale of the products, says H. C. M. Case, chief of farm management in the College of Agriculture, University of Illinois.

"The 'small farm, well tilled' idea was prominent 25 years ago," points out Prof. Case. "As with any form of farming, 50 per cent of the chance for success rests with the individual. Actual farm experience plays a large part in determining a man's chances of succeeding."

No one type of small farm is best. Some people are more successful with poultry, while others succeed better with some specialized fruit or vegetable production or a small dairy farm. Usually the small farm can not well develop many different kinds of production because of the cost of maintaining different kinds of equipment. In a period like the present, when large diversified farms are hardly meeting operating expenses, there is little chance for the small diversified farm.

The small farm, it is explained, should look first of all to the provision of family needs, and secondly, to the development of some one or two important sources of income for which the market is quite definitely assured. The small farm is the most successful and has its most important place in supplementing some income from other sources. But in any event, success depends mainly upon the ability of the farmer to make a good plan and to carry it through.

Oats As Feed For Swine Suggested By Illinois Tests

Wider utilization of oats, which are still extensively produced in spite of the declining market for them, is suggested in a new circular, "Oats as a Feed for Swine," by W. E. Carroll, chief in swine husbandry in the College of Agriculture, University of Illinois, and now available for distribution.

With the disappearance of 800,000 horses and mules from farms and city stalls in Illinois--the chief outlet for the state's 4,500,000 acres of oats--farmers have been casting about for suggested uses of this grain. The usefulness of oats in the cropping system has been the important reason for their retention on Illinois farms, but in view of continued extensive production and the reduced market value of oats, it has been desirable to find some way of expanding their use. Feeding oats to swine under certain conditions and methods is suggested by Prof. Carroll.

More than 1,000 pigs have been fed at the Illinois experiment station since the spring of 1926 in an effort to determine the most profitable way to use oats in swine feeding. The results to date, as summarized in the bulletin are:

1.--Oats can be used extensively in place of corn in the rations of pregnant sows without noticeably reducing the efficiency of the ration. They may also be used in sow rations during the suckling period, but to a less extent.

2.--For growing-fattening pigs, one-third of the ration may consist of oats without reducing the rate of gain compared to the rate when corn is used.

3.--Grinding 100 pounds of oats and feeding them as one-third of the ration saves about 27 pounds of feed as compared with the amount used when whole oats are fed in otherwise similar rations.

4.--Hulling oats and feeding the hulls to growing-fattening pigs is less profitable than feeding ground oats.

5.--Only when oats are as cheap as corn per pound will a ration that contains oats in any form produce as cheap gains as will a ration of corn and a protein supplement.

A copy of this circular, No. 414, "Oats As a Feed for Swine," may be had by writing the College of Agriculture, University of Illinois, Urbana.

-1-

Cleaning Ditches By CWA Workers Is Boon To Farmers

Using CWA workers to clean out ditches and natural channels is helping farmers in one of the most important drainage problems Illinois agriculture faces today, says E. W. Lehmann, head of the department of agricultural engineering at the College of Agriculture, University of Illinois. This work also is bringing benefits to communities and the state at large.

"The problem of cleaning out ditches is a serious one in many localities," explains Prof. Lehmann, "and the lack of a plan for maintenance makes it necessary in many cases to organize so that the work can be done and the cost distributed among the people in the district who are benefited. The use of CWA workers, not only accomplishes this reduction in cost to the farmers, but aids in poor relief efforts, relieves to an extent the pressing problem of unemployment and gives idle workers an opportunity to sustain their self esteem.

"The growth of weeds and brush in many open ditches retards the water flow to a point that the effectiveness of the drainage is greatly reduced, even though the outlet from tiles may be satisfactory under normal conditions."

AGRICULTURAL LIBRARY  
ROOM 225  
NEW AGR BLDG

M

Culling Sows Is Profitable Even Without AAA Program

Getting rid of the poorer sows in Illinois' swine breeding herds would be a profitable way for Illinois farmers to cut their pork cost and at the same time reduce future unwieldy pork supplies, even if there was no AAA corn-hog adjustment program to pay producers for making the reduction, says R. E. Wilcox, of the department of agricultural economics, College of Agriculture, University of Illinois.

The fact that it costs the same to carry a sow whether she produces a large or a small litter makes it a profitable practice to weed out those that give any indication of being poor breeders and poor mothers, he pointed out.

"Cost figures collected by the college, when applied to the present hog situation, show that a 33-per cent reduction in pork supplies could be made under present corn price levels without reducing the total farm profit a cent if the remaining 67 per cent of pork was produced from sows weaning seven pigs to the litter instead of an average of only four.

"Thirty per cent of the cost of raising pigs for market is consumed in feeding, housing and caring for the sows on the average corn-belt farm," explains Prof. Wilcox, in referring to the fact that Illinois farmers may proceed individually, and at the same time collectively through the corn-hog program, in their efforts to adjust production and obtain a profit in swine production.

"Under present price conditions, most Illinois farmers could well afford to cull out and sell five out of every ten sows on the farm, if this culling leaves five sows that will wean three more pigs to the litter than the average of the ten."

This statement is borne out by investigations of 1936 cost records kept by 34 to 37 central Illinois farmers for a three-year period. Figures from these farms show that 79 per cent of the sows weaned spring litters averaging four or less pigs, while another 21 per cent weaned spring litters of seven or more. These two groups were within a few cents of each other in the cost of maintaining a cow.

More detailed information relative to these facts is given in Bulletin 206, entitled "Some Important Factors Affecting Costs in Hog Production." Copies of the bulletin may be had by addressing the College of Agriculture, University of Illinois, Urbana.

-M-

Horse And Tractor Expenses Compared On 1,000 Farms

Two thousand Illinois farmers have proved that whether an operator should use horses or a tractor for power still depends upon the farmer's individual abilities, his financial resources and the particular condition of his farm. There is no basis, so far as net income is concerned, for recommending any one type of power for any large group of Illinois farms.

This is revealed in a study of the cost of horse and tractor power on Illinois farms made by F. E. Johnston and J. E. Wills, of the farm management division of the College of Agriculture, University of Illinois. Details relative to the study have just been made available in Bulletin 206, published by the university agricultural experiment station.

The actual experiences of some 1,000 farm operators, as shown by financial records kept on 1,351 farms in 1930 and 1,500 farms in 1931, were used for this study. Standard tractors, general-purpose tractors and tracks were included.

Many farmers have asked the college if they could increase their net incomes by changing from horse to mechanical power, or from standard to general-purpose tractors. Horse-operated farms, standard-tractor farms and general-purpose tractor farms, according to this new bulletin, were found in general to have the same net incomes when comparison was made between groups of farms comparable in class, although the gross incomes were higher on the tractor farms.

"Corn King" Wins After Seeking Honor For 30 Years

When Clarence Watson, 42-year-old McDonough county farmer of Macomb, won the "corn king" title of Illinois during the recent thirty-sixth annual Farm and Home Week at the College of Agriculture, University of Illinois, he climaxed a 30-year quest that he has been making for corn growing honors in the country's second largest corn producing state.

He won the title when his ten-ear sample of yellow utility corn won the grand sweepstakes in the annual Illinois Seed Gain and Utility Corn Show held in connection with Farm and Home Week. He has been growing and showing utility corn ever since the University of Illinois introduced it more than 14 years ago, but even before that he had been growing and exhibiting seed corn for almost a score of years. However, this is the first time that he has ever won state honors, although he has been getting a little higher every year, he reported.

He is a firm believer in the Illinois' system of permanent soil fertility as worked out and advocated by the college of agriculture. His four-year crop rotation system includes corn, corn, oats and clover, and he uses limestone and phosphate wherever it is needed on his farm. In addition to producing about 100 bushels of seed corn a year, he feeds around 100 head of Hampshire hogs and 50 head of Hereford cattle.

He is enrolled in the farm accounting project sponsored by the extension service of the agricultural college, and for four years has been a member of the agricultural economics advisory committee to the experiment station of the college. He also has served as a director of the Illinois Crop Improvement Association.

He and his father are the only farmers, besides the initial owner, who have ever lived on the 151-acre farm, which he now operates. His father bought the farm in 1870. Both the father, who is 71, and the mother, who is 74, are still living in the cut.

It was in 1910 that Watson first attended the university short courses that have since become the annual Farm and Home Week. That year he won a free trip to the event as a prize on a bushel of seed corn in a local corn show at Macomb. He has been coming to Farm and Home Week more or less regularly ever since.

His prize-winning sample at this year's show was picked out of 1,000 ears grown in a 40-acre field that averaged 60 bushels an acre despite the hardship of dry weather.

Trees May Prove Real Pay Out On Federal AAA Land

Growing trees on land contracted to the government through the AAA wheat and corn-hog adjustment programs will prove more advantageous to farmers in many parts of Illinois than crops planted on the same ground, says L. E. Sawyer, extension forester of the College of Agriculture, University of Illinois and of the Illinois Natural History Survey.

"On a large majority of farms throughout Illinois, where corn-hog and wheat contracts are signed, the less productive land will be removed from cultivation," explains Sawyer. "Under the terms of the contract such land may be planted to trees for woodlot, windbreak or forest purposes. This is a decided advantage to farmers living in northern and central portions of the state. It gives them an opportunity to establish the long-needed protection without reducing the area of the farm that is available for cultivation.

"In many cases this less productive land will grow trees to better advantage than it will grow farm crops, even under more normal conditions. In the future such tree plantings will yield valuable timber crops, or they will aid in the control of erosion, or both."

## Expert Figuring Shows Advantages Of Corn-hog Plan

Terms of the government's corn-hog contract are so advantageous to Illinois farmers that under some circumstances it might be more profitable for them to sign up and not produce as many hogs as all than it would be to go on producing in the old way. These and other "believe it or not" facts are revealed in a series of formulas worked out on the AAA corn-hog contract by Prof. H. H. Risk, Head of the Department of Animal Husbandry, College of Agriculture, University of Illinois.

Under the contract require that cooperators agree to reduce their number of hogs 25 per cent below the average number for 1932-1933 and the number of hogs raised to about 15 per cent below the average of those base years. As compensation, contract signers will get benefit payments of \$5 a head on their hogs minus the local administrative expenses. This will be in addition to the gross sales returns.

While 200-pound hogs can be sold in 1934 for \$147 a hundredweight and assuming that the average feeder cost is \$4 for each 100 pounds market weight, it would be more profitable to sign up and not raise any hogs this year than it would be to ignore the corn-hog program and raise the same number as the 1932-1933 average. It should be remembered, however, that this might leave the producer without a base if the program is continued after 1934. When calculating this comparison Prof. Risk makes a small deduction from the \$5 a head benefit payments to cover the cost of local administrative expenses.

Further proof that the corn-hog plan is fair to the producer is shown by one of Prof. Risk's formulas which proves that with the full \$5 a head benefits, hogs will have to bring \$7 a head in 1934, regardless of weight, before the gross returns of the non-signer will equal those of the farmer cooperating with the AAA. Below a market price of \$10 a head, the contract signer's returns will exceed those of the non-signer; above \$15 the gross returns of the non-cooperator will exceed those of the producer who reduces his production 25 per cent in 1934.

For example, let it be assumed that the contract signer produced an average of 100 head of hogs in the two base years, and in 1934 he agreed to raise only 75 head. If the market price should jump to \$15 a head, he would receive \$1,125 from the sale of hogs and \$575 in benefit payments, or a total of \$1,500. The non-signer will continue to raise his average of 100 hogs and will receive \$15 a head from the sale of the stock, or \$1,500 in gross returns.

When the weight of the hogs is considered and a small deduction from the benefit payments is made for local administrative expenses, Prof. Risk explains that 200-pound hogs must bring an average of \$7.55 a hundredweight before Illinois producers can afford to pass up the opportunity of signing a corn-hog contract. This, of course, is assuming that the non-cooperator will produce the same number of hogs in 1934 as he averaged in 1932 and 1933. The corresponding price for 240-pound hogs is \$8.125 a hundred pounds.

The non-signer who raises feeder pigs to around 70 pounds is gambling that the market value of his young stock will jump to \$21 a hundred, or war-time prices in 1934.

Stockmen Now Have Chance To Pickle With Terminals

Rapid increase in the number of local livestock markets within recent years has put Illinois farmers in a strong position to bargain with the larger terminal markets for a reduction in the marketing expenses on the 175 million dollars worth or more livestock they sell every year, in the opinion of R. C. Abby, associate chief in livestock marketing at the College of Agriculture, University of Illinois.

How prominent local livestock markets have become can be judged from the fact that an estimated 80 per cent of all Illinois hogs moved direct to market in 1932 without going through terminal markets, Abby pointed out.

"If stockmen were sufficiently organized and decided that it were advisable to renew terminal market patronage, they could get to the bottom of the terminal market involved, specify the volume of livestock they were in a position to return to that market and bargain for a reduction in marketing expense.

"This would be in line with the recent agitation of stockmen for a larger patronage of terminal markets. In some sections stockmen have signed up to market all livestock at terminals for a specified period.

"Should stockmen continue their campaign for increased patronage of terminals without organized bargaining for reduced terminal charges in return for increased receipts, they will have overlooked an excellent opportunity. Business men would never pass up such a chance. In the same way organized producers who preferred to keep on patronizing local markets could bargain for a higher price with the alternative of going to the terminal market if the local market did not meet requirements.

"Every terminal stockyards company could handle 50 per cent more livestock than it is handling now and do it at relatively little more cash expense than in handling current receipts. If assured a definite increase in volume of livestock, the company could afford to make concessions in its charges. One stockyards executive said but a few months ago, 'If we could double our volume, our cash handling expense would not be proportionately increased and we could afford to reduce our charges. Speaking for our own company, we would be glad to do it.'

"In one area stockmen already have approached officials of a terminal market as to the reduction of charges in proportion to increased receipts."

Advises Planting Locust Trees On Retired AAA Land

Planting black locust trees on retired wheat and corn land contracted to the Agricultural Adjustment Administration supplies a four-fold purpose that might well be considered by many Illinois farmers, says L. E. Sawyer, extension forester of the College of Agriculture, University of Illinois and the State Natural History Survey. Black locust trees comply with the AAA requirements, they prevent soil erosion, aid in improving the nitrogen content of the soil and in time will furnish a crop of durable fence posts.

"Soil erosion, which is so destructive over a large portion of Illinois," explains Sawyer, "may be controlled easily and economically by planting trees, and one of the best varieties for this purpose is the common black locust. Being a legume, this tree enriches the soil, and where black locust has been planted a heavy sod becomes established within a few years. In addition to its soil-holding ability, black locust produces one of the most durable fence post woods that can be grown in this section of the country. In 10 to 12 years it will often produce posts 4 to 5 inches in diameter."

-M-

Care Of Sows Is More Essential Under Corn-Hog Plan

To get the most out of the "new deal"--which to Illinois farmers means cooperating with the AAA corn and hog adjustment program--producers might profitably give greater attention to reducing spring pig death losses, says W. E. Carroll, chief in swine husbandry at the College of Agriculture, University of Illinois.

The corn-hog contract requires that a cooperater reduce by 25 per cent, not only the number of hogs marketed, but also the number of litters farrowed. Thus getting an allotted number of pigs for market from a given number of litters makes it highly desirable that the producer have reasonable control over the death losses of the pigs. "Only 14 of every 100 pigs farrowed weak live to be weaned, while 90 out of 100 strong pigs live to a weaning age," explains Prof. Carroll. "Then, too, 3 to 15 per cent of all pigs farrowed have no chance of surviving because they are born dead."

The chances of the pigs surviving are determined during the gestation period, and healthy sows are, of course, necessary for healthy pigs, it is said. The kind and amount of feed the sow receives apparently influences the strength of the pigs at birth. For a certain amount of protein and mineral matter are essential for the development of the unborn pigs. A mineral mixture composed of equal parts of limestone, bone meal and salt is as good as any, except in goitrous areas where 1 to 2 ounces of potassium iodide should be mixed with each 100 pounds of the simple mineral. Exercise of the sow during gestation also contributes to the strength of the pigs.

Any of the common farm grains can be used as a basis for the ration for pregnant sows. Legume hay is essential for best results when pasture is not available. Whether to feed protein supplements in addition to the grain and hay will depend largely on the age and condition of the sows. Sows are more likely to need such a supplement than mature sows. One-fourth pound of tankage, one-half gallon of skim milk or one-half pound of soybeans per head will usually suffice and is good insurance against pig-eating in sows craving additional protein the last month before farrowing.

Sows should not be allowed to become so fat that they are lazy and awkward. They should, however, be put in high enough condition to milk well after they farrow.

-M-

AAA Wheat Money Used For Wide Variety Of Necessities

"The butcher, the baker, the candlestick maker"--all are sharing in the \$1,377,851 in benefit payments that have been received to date by more than 26,000 Illinois farmers and landowners who cooperated with the AAA in adjusting their wheat acreage in 1934 and 1935, according to a survey made by the extension service of the College of Agriculture, University of Illinois.

Even Santa Claus got a "lift" in some counties where the government checks arrived before Christmas, while other beneficiaries included doctors, hospitals, insurance companies, grocers, clothing merchants, bankers, implement dealers, threshing men, hired help, and so on along the line.

The wheat benefit payments received so far, it is said, do not represent all that is coming to the farmers from the AAA this year. Before another wheat harvest is over, the total bonus for the 1934 wheat adjustment will amount to approximately \$2,618,000. Further improvement in the Illinois farmer's income is anticipated when the exchange value of the products rural people have to sell is increased as a result of the various AAA programs.

## First 20,000 Farmers Reported In Corn-Hoe Campaign

Sign-up of Illinois farmers in the government's corn-hoe production adjustment program passed the 20,000 mark Tuesday night, February 12, although up to that time progress reports had been received from only 17 of the 103 counties and the campaign was considered only a little more than well started, according to an announcement by Dean Herbert W. Burford, of the College of Agriculture, University of Illinois and director of the agricultural extension service, who is chairman of the state advisory committee on the campaign.

The line-up of the ten leading counties on the basis of incomplete progress reports received by the extension service from county farm advisers up to Tuesday night was: Iroquois, Farm Adviser C. E. Johnson, 1,171; Livingston, Farm Adviser G. G. Turner, 1,237; Bureau, Farm Adviser Paul W. Dean, 1,604; Adams, Farm Adviser S. F. Russell, 418; DeKalb, Farm Adviser E. V. Bakensen, 544; Whiteside, Farm Adviser F. H. Shuman, 800; Kankakee, Farm Adviser G. T. Smith, 115; Hancock, Farm Adviser T. H. Hafner, 124; McHenry, Farm Adviser T. T. Kay, 627, and Grundy, Farm Adviser R. V. Zetser, 170.

Within the next few weeks it is estimated that well over 75 per cent of the eligible producers in the state may join with their neighbors in the voluntary cooperative movement to adjust production to demand and thereby overcome the effects of farm prices that have sunk lower and lower as a result of the loss of foreign markets and other causes. In no county has the campaign been equalled at the present time, and in practically all counties farmers are busy filling in work sheets, and listing supporting evidence and signing contract application.

Approximately 1,000 sign-up stations will be conducted at different points in the state during the campaign to make it easy for every Illinois farmer to see the plan and become eligible for his share of the \$40,000,000 or more in bonus payments to be distributed to cooperating farmers in this state, it was estimated by Prof. J. C. Spittler, state leader of farm advisers. He is representing the extension service of the College of Agriculture, University of Illinois in the campaign.

Again the way for the sign-up, educational meetings have been held in practically all counties of the state by county farm advisers and the extension service of the agricultural college. Sixty-eight of the 103 counties have reported 1,264 meetings attended by 150,333 farmers anxious to learn about the contract and the purpose of the campaign.

Inasmuch as many of the counties holding corn-hoe educational meetings have reported, it is believed that the total number of Illinois farmers who have given preliminary information relative to the adjustment program will amount to 70 per cent more than the 150,333 reported, or 136,331.

F. H. Shuman, farm adviser of Whiteside county, reports that more than 4,500 farmers in that county have attended the corn-hoe educational meetings, the largest total attendance reported to date. Other corn-hoe educational meetings that have reported include Henry, with a total attendance of 4,700; Edgar with 4,060; Crawford and Jasper counties with a combined attendance of 3,700; Grundy county with 4,500, and Christian county 3,353.

Chinch-Bug Count Shows Five Times 1933 Hibernation

Last year chinch bugs reduced the corn crop in 70 Illinois counties from 15 to 50 per cent, and unless May and June of this year are unusually dry, the 1934 damage from this insect may be double that of last year, says W. P. Flint, chief entomologist of the Illinois Natural History Survey in a report of the extension service of the College of Agriculture, University of Illinois. A study of the records of the weather bureau also reveals that the chances are three to one that the two crucial months will be favorable to the chinch bugs.

A recent survey of the former infested areas indicates that there are at least five times as many chinch bugs in hibernation now as at the same time last year, a serious threat to the state's nine million acres of corn. Only the counties in the extreme northern and southern ends of the state are exempt from possible chinch bug damage, explains Mr. Flint.

Possibly 10 per cent of this likely menace can be checked by farmers who will burn over areas where chinch bugs are prone to winter. From 80 to 90 per cent of these over-wintering insects will be found at the bases of bunch-forming grasses, particularly the native grasses such as blue stem, prairie grass, bunch grass and broom sedge. They will be found on the south slopes of ditch banks, roadsides and the south and west sides of holes where accumulations of grass and leaves are evident. From 100 to 5,000 chinch bugs under each square foot of cover have been found on farms in central and north central Illinois.

These favored types of protective cover should be burned off sometime between the first of December and the middle of April, when conditions are dry enough so that the fire will burn close to the ground. Burning against the wind so that the fire will spread slowly is recommended.

It is not necessary, or advisable to burn over whole tracts of woodland or the whole farm, explains Mr. Flint. The bugs are nearly all in the south side of the woods or in the favored localities mentioned previously. Well established stands of blue grass seldom contain large numbers of bugs and should not be burned. It is better to look over the favored hibernating places and concentrate in burning these thoroughly, rather than burning over the whole farm, it is said.

-M-

Market Check-Up Is Near Move After Planned Farming

Now that stockmen and farmers of Illinois and other corn belt states are going in for planned, adjusted production on a larger scale than ever, their next move might well be a shrewd appraisal of the advantages and disadvantages of local livestock markets as against terminal markets, according to R. C. Ashby, associate chief in livestock marketing at the College of Agriculture, University of Illinois.

"Major advantages to farmers of local markets include (1) convenience, (2) no delay in securing returns, (3) some apparent saving in marketing expenses and (4) avoidance of risk of price change, since on short haul deliveries the approximate price can be known before the hogs leave the farm.

"Major disadvantages, less apparent to the farmer and hence frequently disregarded, include: (1) less assurance of accurate weights, (2) non-competitive sorting and grading, (3) payment not guaranteed whereas at terminal markets all sales agencies are under government approval surety bonds guaranteeing payment to shippers, (4) local markets have, on the whole, tended to weaken the level of hog prices and (5) while affording an apparently desirable outlet for hogs, many local markets do not handle other livestock, leaving the producer to dispose of cattle, calves and sheep elsewhere."

-M-

Industrial Rise Is Seen As Boon To 1934 Agriculture

A world-wide reversal from a downward to an upward trend in industrial activity is of basic significance to American farmers, but unfortunately the growing spirit of nationalism in different countries has set up conditions which greatly limit the foreign market outlets, according to the annual state agricultural outlook report just released by the College of Agriculture, University of Illinois.

The AAA program now being applied to export supplies should, however, aid United States farmers in getting full advantage of whatever improvement is made in industrial activity in this country, it is pointed out by agricultural economists of the college. The purpose is to adjust production to the reduced foreign demand while supplying fully the domestic requirements, it was explained.

Improvement in industrial activity looms large in the farmer's hopes, for such activity determines the incomes of non-agricultural consumers and these consumers, in turn, are the principal source of the farmer's income, the report points out.

The latest available index indicates an increase in industrial production in the United States of 26 per cent in 1933 as compared with the 1932 low point, an increase in England of 13 per cent, 17 per cent in France, 23 per cent in Germany, 9 per cent in Italy and 25 per cent in Japan.

This increase in foreign industrial activity would be a more hopeful sign for the American farmer than it is if it were not for the fact that European nations have progressed in their campaigns for agricultural self-sufficiency, the report points out. Improved foreign outlets for U. S. agricultural products apparently must come from negotiation of reciprocal trade treaties, which are of limited possibilities, or result from a devalued U. S. currency, the effects of which would be temporary.

"Germany is now on a surplus basis in rye, wheat and meat. France has begun to export wheat. Italy is self-sufficient in wheat. England has adopted a definite program of increased production of domestic bacon supplies, imports being restricted more than 16 per cent for 1934. The United States quota is only slightly more than 6 per cent of the total British import. As a result of the London wheat conference the United States was assigned a quota of 47 million bushels of wheat exports for 1934 in contrast to 26 million bushels exported in 1933 and 82 million bushels in 1932.

"Agricultural exports constituted 42.9 per cent of the total United States exports during 1909-1914, but only 36.4 per cent during the period 1927-1932. Whereas 14 per cent of our total agricultural production was exported in 1921-1925, only 7 per cent was exported in 1930-1931."

-M-

New Bulletin Sifts Basic Factors In Milk Marketing

A decline of from 10 to 15 per cent in the per capita consumption of milk and cream in important fluid milk markets of the United States during the past several years has been caused principally by retail prices which have been too high in relation to consumers' declining purchasing power, according to results of a study made by Dr. R. W. Bartlett, of the department of agricultural economics, College of Agriculture, University of Illinois. Findings made in the investigation have just been published by the experiment station of the college in a bulletin entitled, "Prices and Consumption of Milk in Specific Cities as Related to Industrial Payrolls and Other Economic Factors."

# The Extension Messenger

COLLEGE OF AGRICULTURE UNIVERSITY OF ILLINOIS

Timely Notes for Farm Advisers and others from the Agricultural College  
Experiment Station, and Extension Service

VOLUME 1

In the first part of the year, the weather was generally favorable for the growth of the crops. The soil was moist and the temperature was moderate. The crops were planted in the early part of the season and they are now in the hands of the farmer. The weather is now becoming cooler and the crops are beginning to mature. The farmer should be careful to watch the weather and to take proper care of his crops.

The second part of the year has been a busy one for the farmer. He has been working hard to get his crops in and to take care of his stock. The weather has been generally favorable, but there have been some periods of drought. The farmer should be careful to water his crops and to take care of his stock during these periods.

The third part of the year has been a busy one for the farmer. He has been working hard to get his crops in and to take care of his stock. The weather has been generally favorable, but there have been some periods of drought. The farmer should be careful to water his crops and to take care of his stock during these periods.

The fourth part of the year has been a busy one for the farmer. He has been working hard to get his crops in and to take care of his stock. The weather has been generally favorable, but there have been some periods of drought. The farmer should be careful to water his crops and to take care of his stock during these periods.

The fifth part of the year has been a busy one for the farmer. He has been working hard to get his crops in and to take care of his stock. The weather has been generally favorable, but there have been some periods of drought. The farmer should be careful to water his crops and to take care of his stock during these periods.

The sixth part of the year has been a busy one for the farmer. He has been working hard to get his crops in and to take care of his stock. The weather has been generally favorable, but there have been some periods of drought. The farmer should be careful to water his crops and to take care of his stock during these periods.

Grass Seed Used Doubled by AAA and Other Programs

Thousands of farmers in Illinois now taking part in the government's corn-hog and wheat adjustment programs will as well as look to their immediate supply of clover and hay seeds on hand, for the demand this spring may be double that of previous years, says J. C. Hackleman, crop extension specialist of the College of Agriculture, University of Illinois.

It is anticipated that approximately 1,700,000 acres of Illinois corn land may be retired from production under the AAA corn-hog contracts, while last fall some 375,000 acres were withheld from normal wheat seeding as a result of the federal wheat production control program. It is likely that these nearly 2,000,000 acres will be planted to soybeans or grasses--and these are heavy applications to all the tonnage produced in Illinois in either last or 1935.

Additional demands are being made on the market for grass seed, such as a result of other governmental activities, such as the federal soil erosion service, work of the civilian conservation corps, civil works administration projects and the Tennessee valley project.

"Large seeds in general are not as plentiful as in previous years," points out Prof. Hackleman. "The supply of alfalfa seed, clover and timothy clovers at the close of the 1934 harvest was slightly in excess of normal demand, but probably not sufficient to meet the current demands as a result of the AAA programs. Since harvest, however, alfalfa and timothy seeds have been leaving our shores in much greater quantities than any previous year.

"The 1934 September-December export of alfalfa seed was nearly twice the average for the last period in the 11 years of 1923 to 1933, inclusive. Likewise, red clover exports during the same three months of 1934 were 1 1/2 times as great as the 11-year average normal demand. Timothy and other grass seed exports were relatively much less significant in view of the normal supplies and the normal demand of these seeds at this season of the year.

"Illinois harvested the largest crop of soybeans in 1934, also it has had in several years, owing to a reduced acreage and the low yields resulting from late plantings. Soybean processors anticipated their needs by early purchases in October, November and December of last year, and half of the threshing has already been in their hands. The remaining beans that meet the normal demand for seed are approximately 75,000 acres in Illinois, as well as planting contracted acres to be turned under.

"Thousands of bushels of cow pea and Korean lespedeza seed will be needed in southern Illinois for seeding on converted land that is too acid or too low in phosphorus to grow alfalfa, red, alsike or mammoth clovers.

"The supply of grass seed, however, is more nearly adjusted to meet anticipated demands.

"It is advisable for farmers who have a limited supply of home-grown clover seed on hand to send cleaned samples to the state analyst for examination, so that they may be ready to sell any extra supply. Illinois farmers who do not have sufficient seed on hand to fill their requirements should make the necessary arrangements immediately," says Hackleman.

In this connection it was announced last the U. S. Department of Agriculture has just issued a new mimeographed circular entitled, "Pasture Plants and Pasture Mixtures Suggested for Seeding on the Average Tonnage out of Cotton, Tobacco, Wheat and Corn for Erosion Prevention and Soil Improvement."

AAA Dairy Plans Tough Estimate Illinois Industry

Illinois would take front rank prominence in any dairy production adjustment program such as recently outlined by Secretary of Agriculture Henry A. Wallace, for the state stands fifth among all states in total milk production, it is pointed out by members of the dairy department, College of Agriculture, University of Illinois. During the past four years the average annual cash income from the sale of dairy products off Illinois farms has been about 71 million dollars.

The tentative plan which the administration is offering to the dairy industry is an individual voluntary acre allotment proposal financed by a processing tax on all butterfat in milk and its equivalent and a compulsory tax on oleomargarine. The rate of the processing tax would eventually reach 7 cents per pound of butterfat in all milk and its equivalent and the compulsory tax on oleomargarine equivalent to the tax rate on butter.

A three-year base period, with individual production of butterfat for 1941, 1942 and 1943 established for each farmer, is contemplated.

The goal to be set for individual production will be percent in milk and butterfat production over a period of years based on the quantities sold in the past year, with the expectation that the total will be one-half of the national production.

The method of securing production of the year is to be left to the judgment of cooperating producers. Cooperation by producers is to be secured through benefit payments or premiums on sales based on production basis and not on acreage.

Fewer and better cows, superior high quality products, more economical and more profitable costs have been the major aims Illinois farmers have been of long hard improvement cooperation and educational activities of the College of Agriculture, University of Illinois. It is pointed out by members of the college. It appears, however, that more definite steps are now being taken. Secretary Wallace himself has said that, "If you could not cooperate in a program not dictated upon, the path of the dairy industry is lined up to be rough. Our course will be determined by the response of dairy farmers and their representatives to this program."

-34-

Breeding Quality Small Fruits Now Being Made Easier

Small fruit growers, including both the home-gardener type and the commercial producers, this spring will have the best chance that they have ever had to get started with superior, high-quality varieties at a reasonable cost, according to Dr. A. S. Colby, chief in small fruit culture at the College of Agriculture, University of Illinois. Nevertheless, prospective buyers should be sure that the varieties they buy are adapted to the climatic, soil and other conditions in their particular locality.

During the past several years many small fruits have been developed through controlled methods of plant breeding which are greatly superior to the older varieties, formerly standard, Dr. Colby said. Many of these newer varieties might well be given a place in the 11,000 acres or more of small fruits that were reported for Illinois in the last census, he said.

Most nurseries are cooperating with the state nursery inspection service to grow and sell only disease-free stock, usually true-to-name, points out Dr. Colby, and the prospective buyer may purchase from any one of several reliable nursery firms with the certainty of getting high-class plants.

New Sign-Up Gain for E. Ribes, Sec. Agricultural

Possibilities for further adjusting the acreage of wheat on Illinois farms have been brightened by a telegram which Dean Herbert W. Landis, of the College of Agriculture, University of Illinois, has received from AAA headquarters in Washington announcing the reopening of the wheat sign-up to admit any farmers who could not or did not sign up last fall. Plans for extending the Illinois sign-up were started immediately upon receipt of the telegram.

Illinois farmers, guided by the teachings of the College of Agriculture, University of Illinois already had reduced their average of all wheat to one cent since 1915, but they went even farther in the AAA sign-up last fall and put the state in fifteenth place among all states as the percentage of wheat acreage reduced. The 1,011,204 acres that were put under contract in the 14,150 contracts signed last fall represented more than 50 per cent of the state's average acreage during the three-year base period, 1934-1936. The total required reduction under the terms of the contracts was about 1,000,000 acres, or 100,000 acres below the average for the 1936-1938 base period.

Reopening of the sign-up in the AAA program is no way to further adjustments. Growers who are under contract for the final 1937 benefit payments and for subsequent benefits on the 1937-1938 contract, but not for the first 1937 benefit payment which already has been paid. A special provision of the regulations will make it possible for a contract to be drawn for the farmer who had an unsatisfactory base acreage under the original plan, but the new contracts will not give late signers an advantage over original signers.

The 14,150 contracts of AAA wheat production control regulations which were organized following the signing of the sign-up last fall were used in extending the sign-up under the plan announced in the 7th annual report of the state by Prof. E. C. Landis, state leader of the program, and in conducting the attention service in the College of Agriculture, University of Illinois on the various AAA programs.

Sweet Clover Helps E. Ribes, in Soil Conservation

Virtually one-tenth of the crop acres in Illinois are to be saved from production in 1938 through the AAA working soil conservation and soil conservation and improvement practices adopted by farmers. Landis, state leader of the state's soil conservation program, says that sweet clover is one of the best soil builders and soil conservers, says A. T. Lang, assistant chief of soil experiment fields, College of Agriculture, University of Illinois.

Sweet clover has proved its value in the prevention of soil erosion and its regular use as a green manure crop as affected by drought losses from the Illinois soil-conservation fields. At the Dixon field, on a soil of good productivity, sweet clover in a rotation of corn, oats and wheat improved the soil to the extent of 17 bushels of corn an acre annually, on a three-year average, when it was the main fertilizing constituent. Where wheat and oats straw were returned to the land, they enhanced the value of sweet clover as a soil builder by 7 bushels of corn an acre. At Mt. Morris in Ogle county, with a fertility level approximately the same as at Dixon, residues from timothy, soybeans, red clover and alfalfa fall short of supplying the benefits of sweet clover combined with oat and wheat straw on the Dixon field by 30, 17, 1 and 7 bushels of corn an acre, respectively.

-17-

### Cats Smut Takes Heavy Toll On Farms Of Illinois

Last year oat smut extracted a tax of approximately 4,888,000 bushels from Illinois farmers, and a similar oat loss may be expected in 1934 unless growers properly treat their seed to prevent this common disease, says Benjamin Koehler, associate chief of crop pathology at the College of Agriculture, University of Illinois. This toll amounts to an average loss of 1.5 per cent of the oat crop for the state, and although the disease is an easily-controlled one, oat damage on some farms amounted to as high as 25 per cent last year, it is said. For control, two treatments--the formaldehyde and the Ceresan--are recommended.

The most satisfactory way of applying formaldehyde to the oat seed is the 50-50 method, which is practically a dry process. A pint of commercial formaldehyde is mixed with a pint of water in a quart-size sprayer of the kind used in gardens and cow sheds. As one man shovels the oat seed from one pile to another, an attendant handles the sprayer, giving the oat "shots" of the liquid on each scoopful of oats as it is picked up. About a quart of the formaldehyde-water mixture should be applied to each 50 bushels of seed.

After this has been done, the oats should be turned over again by shoveling the seed into another pile, or into sacks or a wagon box. If the seed is not sacked, it should be covered with canvas or tarp cloth for at least five hours. The oats are then ready to use or may be stored for several days without serious damage. The cost of this method is about two-thirds of a cent a bushel.

New Improved Ceresan, another recommended disinfectant for treating oats, is a dry dust which should be applied at the rate of one-half ounce to each bushel of seed. It is best to mix it thoroughly with the grain by means of a regular treating machine or a concrete mixer. If the mixing is thorough, the oats can be seeded at once, otherwise the seed should be covered with canvas or sacked and stored overnight. Storage for longer than a few days or a week, however, will reduce the yield.

While this latter method is a little more expensive, costing about two cents a bushel, it helps control other diseases that are sometimes present in addition to smut, it is said.

### Local Fights To Replace or Terminal Livestock Markets

Unless local and terminal livestock markets can be better coordinated or new influences change existing conditions, the vast terminal markets which have been built up in this country must eventually give way to the newer local agencies, predicts R. C. Ashby, associate chief in livestock marketing at the College of Agriculture, University of Illinois. This conclusion is supported by the findings of a three-year study by Ashby which shows the effects of the operation of local livestock markets upon terminal markets.

Local livestock markets have greatly decreased the hog receipts of the terminals, Ashby found. Until 1911, hog receipts at the public stockyards exceeded the federally inspected slaughter, but by 1931 terminal receipts amounted to only 77 per cent of the hogs inspected by federal authorities. In 1931 but 7 per cent of all hogs slaughtered under federal inspection were purchased outside of the public markets, while 10 years later this figure had increased to more than 40 per cent. Then, too, local markets have decreased supplies of hogs available for sale on the public markets even more than they have reduced receipts. At Chicago in 1931, more than 74 per cent of the hogs received were not offered for sale on the open market. Moreover, operation of local markets has tended to lower the quality of terminal market receipts, particularly at Chicago.

## CONTRACTS FOR THE YEAR 1923

A total of 107 contracts for the year 1923 were made on April 1, 1923, just after the close of the 1922 season. The total value of these contracts, the cost of farm machinery, was \$1,000,000. The total value of the contracts, the cost of farm machinery, was \$1,000,000. The total value of the contracts, the cost of farm machinery, was \$1,000,000.

During the year 1923, the total value of the contracts was \$1,000,000. The total value of the contracts, the cost of farm machinery, was \$1,000,000. The total value of the contracts, the cost of farm machinery, was \$1,000,000.

For a list of the names of all the contractors for 1923, see the list of R. J. Leide, of Melrose, and the list of R. J. Leide, of Melrose, and the list of R. J. Leide, of Melrose.

The report of the contractors for 1923, the total value of the contracts, the cost of farm machinery, was \$1,000,000. The total value of the contracts, the cost of farm machinery, was \$1,000,000.

Seed Mixture For AAA Acres Include Several Choices

With probably a hundred forage plants to choose from, Illinois farmers taking part in the AAA corn-hay and wheat adjustment programs have a singular opportunity to restore some of their old permanent pastures or seed new ones on the retired acres, says J. J. Pieper, associate chief of the crop production at the College of Agriculture, University of Illinois. At least 25 of these crops are used more or less commonly in the state.

To make the most of their opportunities farmers must select the ingredients for their pasture mixtures that are best adapted to the soil and that at the same time fit the needs of the grower.

Kentucky bluegrass is one of the most popular for pastures, explains Pieper, and is adapted to the better soils somewhat inclined to be sweet. Timothy has a wide adaptation for fertility and drainage in all parts of Illinois, while alfalfa is a favorite on poor, acid and wet land where other grasses find it difficult to get a stand.

White clover is the most important permanent cover crop for all soils and is well on poor, acid soil. vernal and winter annuals such as the red and yellow clover, alfalfa, sweet or red clover, and the vernal and winter annuals such as the vernal and winter annuals may be substituted in the above mixtures for alfalfa or white clover.

Mixtures of these crops are advised for permanent pastures on the various types of soil, together with the amount to be sown per acre are recommended by Pieper as follows:

Good, well-drained land--Kentucky bluegrass 5 pounds, red top 3, timothy 4 and alsike and white clover 3 pounds each.

Wet fields--Red top 4 pounds, timothy 4, meadow fescue 4 and alsike clover 3 pounds.

Poor, acid soils--Orchard grass 5 pounds, red top 4, Canada bluegrass 5 and alsike clover 3 pounds. Legumes may be substituted for alsike clover in the northern half of Illinois.

Shaded areas--Orchard grass 5 pounds, rough meadow fescue 5, red fescue 4 and alsike and white clover 3 pounds each.

Where the soil is sweet and fertile, alfalfa or red clover may be added to the above mixtures or used to replace other legumes at the rate of 4 pounds for the acre for alfalfa and 3 pounds for the red clover.

-11-

Chinch-Bug Invasion Will Not Catch Farmers Unaware

Although chinch bug threaten the heaviest invasion in many years, the destructive insect will not catch Illinois farmers unaware, says D. E. Livingston, associate in rural sociology at the College of Agriculture, University of Illinois. During March and April some 417 rural community units located in all parts of the state will hold their regular monthly meetings at which time the chinch bug and recommended methods of control will become almost a campaign issue as the chief topic for discussion. From 1 to 23 such groups will meet in every Illinois county.

Burning over areas where chinch bugs are prone to winter, rotation in crop rotations, use of chinch-bug resistant crops and other suggested control practices will be included in the discussions at the community meetings. Farm advisers, local farmers, members of the college extension staff and entomologists of the Illinois Natural History Survey will be the featured speakers.

Community action, as the result of an educational campaign through rural organizations which make up the 417 community units, is believed to be more effective in fighting combat practices. Through group action, the burning of railroad right-of-ways has been accomplished in some localities, and where the danger of killing wild life is small, other public waste places commonly infested with chinch bug may be cleaned up.

-14-

Yellow Field Corn In Lincoln and Certain Other

"Believe it or not," we have such an effective use of an acid fertilizer on a 100-acre farm that it has been a success for the year. When we have the benefit of limestone on our soil, it is better than any other. The soil will experiment with the use of limestone, says C. J. Fallon, a scientist with the Illinois State University of Agriculture, University of Illinois.

Experiments with the use of an acid fertilizer on the "acid soil" is revealed in the results of four years of tests at two soil experiment fields of rather low productive levels maintained by the state university.

At the Sparta field in Randolph county, where the soil is a light sand with 1.4% lime, the use of manure gave a yield of 7,000 pounds of soybean hay to the acre, but when limestone was applied in addition to manure, the yield of hay was 1,700 pounds an acre. In fields that received a treatment similar to that of the manure where manure had been given. The increase in yield from limestone, when it was applied in addition to manure, amounted to 1,700 pounds, or more than a half a ton to the acre.

In Macomb county, the 100-acre field consisting of a yellow-gray silt loam gave a much better yield of 10,000 pounds of soybean hay to the acre when 1,000 pounds of limestone was applied in addition to manure. The yield of hay was 1,700 pounds, or more than a half a ton to the acre.

The amount of manure used was about 50 tons to 50 acres, while the response to manure applied to the same acre was 1,700 pounds an acre. However, manure on limestone gave a return of 1,700 pounds of hay to the acre, over the plot which did not receive any manure.

11

How to Keep Animals Healthy and Safe

With the ever increasing demand for food and fiber, the need for more and better food and fiber is ever increasing. It is a fact that in many of our states, such as Dr. Robert Graham, chief of animal pathology and hygiene at the College of Agriculture, University of Illinois.

Prevention of the disease in animals is a matter of common sense, and it is the responsibility of the farmer and the veterinarian. It is the responsibility of the farmer and the veterinarian to keep the animals healthy and safe. It is the responsibility of the farmer and the veterinarian to keep the animals healthy and safe.

The disease is a common one, and it is the most common one of loss of production, such as winter and early spring. At the top, the principal organs affected are the liver and kidneys.

Symptoms are febrile, anorexia, loss of appetite, and finally inability to stand, followed by unconsciousness, and death. Symptoms, points out Dr. Graham. Death may occur in one to six days after the appearance of the symptoms, and rarely do animals recover.

Even with the best of treatment, the usual victims of the disease, though it occasionally may be observed in other animals, only one lamb. Non-cremated ewes are most common, and it is a rule that one should not give a lamb an increased respiratory burden over that which it can bear. Toxin products of the unborn lamb, when discharged in the maternal system, are factors in the disease. The only satisfactory explanation of the disease has been reported.

Wheat Cash Has Paid Half Million In Old Farm Debts

Nearly a half million dollars in old debts have been paid off this winter by Illinois farmers who signed up in the AAA wheat adjustment program, if a survey of the use of the first benefit payments made in Macon county may be considered as a barometer for the state, says Marshall Harris, of the agricultural economics department, College of Agriculture, University of Illinois. In addition, some \$202,418 in current debts have been liquidated with funds from the same source.

According to the latest figures available, \$1,511,733.88 in wheat benefit payments have been received by farmers in the state who agreed to reduce their 1934 wheat acreage 15 per cent below their average production during the three years of 1930-1932. A check of the use of this money in Macon county indicates that 51.14 per cent of it went for the payment of old debts and 48.86 per cent was paid on current accounts. When these percentages are applied to the total Illinois wheat payments to date, they indicate that some \$781,170 of rural obligations have been cleaned up.

Macon county is considered as typical of the state's wheat producing area, and it is believed that the use of the benefit money there is applicable to the nearly 25,000 growers who signed up in the wheat adjustment program in Illinois. As the Macon county growers came to the county wheat control office for their acreage, they were asked by Farm Advisor C. G. Lewis to fill in a questionnaire indicating how they intended to spend the money.

Less than 6 per cent of the benefit money was not used immediately, according to the survey, indicating that the farmers put the cash back into active circulation in a short time, where it aided in improving the financial condition of business in general.

Other uses for the benefit money claimed to apply the benefit payments and the percentages concerned by each were: purchase of feed and plowing \$3.85 per cent, machinery 3.24, repairs 2.85, taxes 2.75, labor 2.44, live stock 2.05, seed 1.54, household and personal 1.27 and miscellaneous expenses 1.1 per cent.

Continued wise utilization of AAA benefit funds to clean up old indebtedness and to supply the current necessities of the farm and home will be such to relieve agricultural economic conditions and to start the wheels of industry functioning normally, it is pointed out.

-4-

Illinois Turkey Producers Covarise To Push Quality

It may be a long time until people will be thinking about giving a Thanksgiving or Christmas turkey, but Illinois turkey growers already have started plans for educating consumers to the superior quality of this state's birds, while at the same time further improving that quality.

For the first time, turkey growers of the state have organized a state association, and chief among their objectives will be the matters of consumer education and quality improvement, according to F. E. Alp, poultry extension specialist of the College of Agriculture, University of Illinois, who is assisting with the project.

Illinois was producing more than 91,000 turkeys annually, according to the last census, but most of the turkeys sold to Illinois consumers were range-fed birds from Texas, Alp pointed out. Turkeys produced in Illinois are of superior quality because they are fattened in closer confinement, he explained.

Earl Kennedy, of Ansoy, was elected first president of the turkey growers' association when the organization was formed at the recent meeting in Bloomington.

Record Tree Crop Being Set Out In Illinois This Year

A record number of 151,000 trees are being put out on Illinois farms this spring as part of the plans to speed up the proper utilization of land and bring about better planned agricultural production, according to L. E. Sawyer, forestry extension specialist of the College of Agriculture, University of Illinois and of the Illinois Natural History Survey. This total of 151,000 trees is the largest on record for any one year in forestry projects sponsored by the extension service of the agricultural college and other agencies, Sawyer said.

Almost half of the 151,000 trees, or about 80,000 of them, are black locust that will be planted for erosion control and the holding of blow-down land in different parts of the state. Twenty-five thousand of the black locust trees are going to farmers in Schuyler county for an erosion control project which Farm Adviser L. E. McKinzie is conducting in cooperation with the extension service of the agricultural college. The First National Bank of Aranzville, Cass county, is putting out 22,000 black locust, red pine, pitch pine, white ash and Norway spruce trees.

About 32,000 pitch pine trees will be planted on sandy soils and on worn out farm soils as a timber crop. In addition about 10,000 Norway spruce and white spruce are being planted for Christmas trees and for windbreaks. One planting of 20,000 Christmas trees is being made in DeKalb county, and another of 10,000 in Livingston county.

There are also about 8,000 red pine trees in the 151,000 that will be set out this spring, and the rest are ash, maple and a variety of other species that are to be used in reforestation work. The plantings will be scattered in Hardin, Edwards, Richland, Johnson, Williamson, Vermilion, Piatt, Fulton, Clark and McLean counties, in addition to the several counties mentioned.

Planting for the 151,000 trees is being forward at a time when the outlook for forestry is much brighter than it has been for several years, Sawyer pointed out.

-1-

AAA Programs Will Cut Costs On Many Illinois Farms

With less corn and wheat and fewer hogs to tend, one thousand of Illinois farmers participating in the government's AAA programs will have an opportunity to reduce their operating costs in 1934, particularly in the case of labor and power, in the opinion of J. W. Wills, of the farm management division, College of Agriculture, University of Illinois.

On a great many farms, says Wills, there will be less spent for fuel and other tractor costs; and the expenses for horses can be reduced, if the animals are fed according to work done. If extra labor is normally hired for field work and hog production, it is possible that AAA cooperators may be able to reduce this item of expense.

On farms where the operator and members of his family perform all or nearly all of the work, the chief problem will be to use the existing supply of labor to good advantage. In such cases, it will be possible to give more time to a number of practices known to pay well, yet requiring little or no outlay other than labor.

Among these practices might be included the careful selection and testing of seeds, testing of soil for limestone and phosphate requirements, more efficient use of manure, better control of weeds, keeping machinery in repair, control of livestock diseases through sanitation and the keeping of farm accounts. To this list should be added the opportunity that many farmers will have to make much-needed repairs on their improvements and to "dress up" the general appearance of the farms.

## 110,000 Mark Reached in Illinois Corn-Hog or Corn-Hog

Workers in the Illinois Corn-Hog campaign entered the last two weeks of the campaign with incomplete results indicating that the 110,000 mark in completed contracts had been passed. Through additional contracts are in sight so that a total of 125,000 or more is not improbable for Illinois by the time of the deadline at 6 o'clock, Saturday evening, March 17. It was announced by Prof. J. C. Miller, state leader of farm advisers, who is representing the extension service of the College of Agriculture, University of Illinois in the Corn-Hog campaign.

Up to Tuesday noon, March 20, the state total actually reported in reports from farm advisers stood at 103,270. However, there were 22 counties from which up-to-date reports had not been received at that time.

The 22 counties from which late check-ups had been received announced that they had a total of 51,825 completed contracts. This is an average of 2,350 for each county, a mark high enough to put the state total well over the 110,000 line if it holds for all the 102 counties of the state.

McLean county, the largest in the state in number of farms and in corn and hog production, took the state lead for the first time when the regular weekly reports brought a new total of 3,287 contracts from Farm Adviser I. G. Lattle. The other county, Lincoln, was just the 3,500 mark to a total of 3,167 contracts reported by Farm Adviser I. T. Turner, while the other counties had between 2,000 and 3,000 contracts.

Troopers had 2,973, LaSalle 2,600, Champaign 2,460, Vermilion 2,440  
Bureau 2,320, Shelby 2,317, Henry 2,243, Sangamon 2,100 and Whiteside 2,000

Totals for the other counties of the state were as follows:

Adams 1,782, Bond 751, Boone 330, Brown 714, Calhoun 450, Carroll 1,060,  
Cass 704, Christian 1,510, Clark 904, Clay 440, Clinton 253, Coles 1,178, Cook 52,  
Crawford 660, Cumberland 900, DeKalb 1,712, DeWitt, 1,204, Douglas 1,977, DuPage 30,  
Elgar 1,325, Edward 475, Effingham 720, Fayette 1,716, Ford, 1,350, Franklin 400,  
Fulton 1,500, Gallatin 613, Greene 1,242, Grundy 1,147, Hancock 1,711, Henderson 900,  
Jackson 400, Jasper 1,040, Jefferson 615, Jersey 364, JoDaviess 1,390, Johnson 632,  
Kane 464, Kankakee 1,153, Kendall 945, Knox 1,523, LaSalle 170.

Record Milk Cow Population Adding to Dairy Problems

The heaviest population of milk cows that Illinois and the United States have ever had is one of the basic facts that farm leaders and officials of the Agricultural Adjustment Administration are up against as they set about working out a solution of the dairy problem, it is pointed out by dairymen of the College of Agriculture, University of Illinois.

Tentative plans for milk production control will be presented by the AAA at a series of regional conferences to be held in the near future at central points in leading dairy producing sections of the country, according to official announcements received by the extension service of the agricultural college.

There are 1,165,000 milk cows on farms of Illinois and more than 26 million on farms of the nation this year, according to figures compiled by the college dairymen. For Illinois this is an increase of 15 per cent over the 987,000 reported for 1928 and an increase of more than 23 per cent over the 883,000 milk cows reported 34 years ago. For the United States as a whole the present population of milk cows is an increase of almost 18 per cent over the total of 21,219,000 reported for 1928.

Whatever plans are made for coping with this problem will figure prominently in Illinois farming operations, because this state is the fifth most important one in total milk production, it was pointed out by officials of the college. During the past four years the average annual cash income from the sale of dairy products off Illinois farms has been almost 71 million dollars, but problems of the industry have reduced that income to as low as 50 million dollars annually during the past year or two. In 1932 dairying ranked first as a source of cash to Illinois farmers, returning 25.7 per cent of their total cash income.

The percentage increase in milk cows has been much greater than the increase in human population during the same period, it was explained. Fewer and better cows producing higher quality products at more economical costs have long been urged upon Illinois farmers by the extension service of the College of Agriculture, University of Illinois. Many herd owners have profited by following this suggestion, but it appears that more drastic steps are necessary. Even though most of the milk and milk products have been finding their way to some market, the returns to farmers have been dangerously low.

The goal of the proposed production adjustment program would be to bring about better returns to producers of all dairy products by bringing production more nearly into line with effective demand. Such a program would be supported and supplemented by milk marketing agreements, drawn in accord with the recently adopted policy which places emphasis upon prices paid to producers.

-M-

Brighter Outlook for Higher Quality Fruit This Year

With more money in circulation now than at any time in the past three years and prospects for short crops in certain areas, Illinois fruit growers anticipate larger premiums to be paid for high quality fruit in 1934, says R. S. Marsh, horticultural extension specialist at the College of Agriculture, University of Illinois. To obtain these premium prices, advises Marsh, orchard men who still have prospects for a crop should carefully plan and organize their spray programs so as to produce the highest quality fruit, especially from the remaining peach crop. Now is the time to see that all spray equipment is in first-class condition and that the latest recommended spray schedule is at hand. Growers may obtain the newly-revised spray schedule, Circular 333, which gives the latest facts for the control of disease and insect pests, from their county farm adviser or by writing the College of Agriculture, University of Illinois, Urbana.

-M-

Discussion Leaders Trained To Aid In Rural Problems

Illinois farmers will be better prepared to cope with new economic and social trends affecting agriculture in the future, as a result of plans now being made to train community discussion leaders and to hold regular community discussion meetings, predicts D. E. Lindstrom, associate in rural sociology at the College of Agriculture, University of Illinois.

The value of community discussions has been demonstrated by the nearly 3,000 AAA corn-hog and wheat adjustment meetings held throughout the state in recent months, it is said.

Several Illinois counties are now training discussion leaders and organizing discussion teams in various types of community units. Training schools, attended by approximately 150 rural people from 50 different community units, have been conducted in Champaign, Ford and Sangamon counties for the purpose of developing discussion leaders. Similar schools will be held in other counties during 1934 so that farm and home bureau units, granges, community clubs and like organizations may provide their memberships with a better understanding of the new economic and social developments affecting farm life.

"The importance of discussion in rural community meetings was recognized by the Agricultural Adjustment Administration when launching both the wheat and corn-hog programs," points out Lindstrom. "A total of 752 community meetings attended by approximately 28,000 farm people were held in 49 Illinois counties by farm advisers and the extension service of the agricultural college in connection with the wheat adjustment campaign. Later there were 2,027 community meetings conducted in 102 counties to discuss the corn-hog program. The latter gatherings were attended by 191,867 of the 214,000 farmers of the state. Thus the corn-hog campaign reached more than 90 per cent of the farm operators in Illinois.

"By training leaders who can conduct discussions at rural community meetings, Illinois farmers will be better prepared to develop future cooperative activities related to their industry."

-14-

Spring Repair Of Farm Machinery Saves Money And Time

With an investment of more than \$160,000,000 in farm implements and machinery, or an average of \$748 on each farm, Illinois farmers can well afford to devote a certain amount of time in the early spring months to making minor repairs and adjustments that assure longer life and more efficient operation of their machines. This is the opinion of E. G. Johnson, agricultural engineering extension specialist of the College of Agriculture, University of Illinois, who points out that thousands of dollars are lost annually by farmers of the state who fail to make necessary machinery repairs before the rush of field work begins.

Lower operating costs and getting the job done on time are awards which the farmer receives who follows the practice of inspecting each machine, replacing badly worn parts, tightening bolts, making adjustments and applying paint when needed, it is explained. The farm machinery instruction book provided by the manufacturer with each machine is of valuable assistance, and the farmer who does not have such a booklet should request one from the nearest branch house.

To give additional assistance in this important problem, the agricultural engineering department of the College of Agriculture, University of Illinois, has published a booklet on "The Care, Operation and Adjustment of Farm Machinery." A copy of this circular, No. 309, may be secured upon request from the agricultural college at Urbana or from county farm advisers.

## Illinois Dairy Plan Details Of AAA Plan

Farmers in various parts of Illinois, which rank as dairy state, have before them for consideration and acceptance or modification the first official details of the proposed plan for a dairy production adjustment program under the Agricultural Adjustment Administration. Farm advisers, extension workers of the College of Agriculture, University of Illinois and others who may be more or less closely connected with the preliminary field work have just been given the tentative details of the plan as revealed in an official telegram and other communications which Dean Herbert J. Mumford, of the College of Agriculture, University of Illinois received from headquarters at Washington.

Farmers have five or six months from the first of April to study the proposal and decide what they wish to do about it. Starting April 1 a series of regional conferences will be held to present more details of the proposed program to farmers for discussion, acceptance or modification.

Just when and where the conference in the Illinois area will be held has not been announced, but officials at the College of Agriculture, University of Illinois are expecting word on this in the near future.

Illinois has a large stake in the program, for the state is the total ranking one in total milk production, and more than 75 per cent of all the cash income of Illinois farmers come from dairymen. During the past four years the average cash income from the sale of dairy products on Illinois farms has been almost 24 million dollars, but during the past year or two this income has averaged as low as 50 million dollars, a condition which the proposed program is designed to correct.

The aim in the plan to restore the purchasing power of dairy farmers will be to hold production at about the level of recent months. This will mean that cooperating dairymen will have to reduce their sales by from 10 to 20 per cent below the peak in 1932 and 1933.

In addition to the higher prices that might be expected to result from the adjusted production, benefit payments are to be paid to cooperating producers at the rate of about 40 cents for each pound of butterfat or about \$1.50 for each surplus 100 pounds of fluid milk that the cooperator reduces.

The program is to be financed by a processing tax starting at one cent a pound on butterfat and advancing to five cents a pound as supply comes under control. The plan is a \$105,000,000 one providing for extension to \$300,000,000 in event of congressional action pending legislation.

Additional features of the program include the relief distribution of surplus milk to underfed children and the transfer of cows from surplus areas to needy farm families. There is also the provision for disease eradication measures.

### Rich Illinois Soil Adds Full Share To Erosion Toll

Even the soils of central Illinois, once thought to be of inexhaustible fertility, are contributing their share of good soil to the three billion tons of soil material which erosion is washing off the fields of the United States every year, according to F. A. Fisher, Illinois regional director for the soil erosion service of the U. S. Department of Interior.

The entire seven inches of richest top soil has been washed off of 47 per cent of the first two sections of land that were surveyed in the erosion control project which the Department of Interior is starting in McLean county, Fisher reported. This is all the more striking in view of the fact that the land has been farmed intensively not less than 100 years. The injury throughout the area is probably not as great as this, but the damage as a result of the erosion that has been going on all these years is severe, he pointed out.

It takes Nature about 400 years to build a single inch of productive top soil from raw sub-soil clay, indicating that it will take between 2,000 and 3,000 years to repair a wound like in the McLean county area, Fisher said.

Erosion is estimated to be causing the farmers of the United States \$400,000,000 a year in destroyed land, loss of plant food and through other channels. The evidence of what soil erosion is doing to McLean county, is proof that farmers in that section and in other parts of the state are paying their full share of the toll, Fisher said. Approximately half the 30,000,000 acres in Illinois are now subject to erosion of one kind or another.

Demonstrations are now being started in the McLean county project to show farmers how to hold their soils in place by means of gully bars and other mechanical devices, how to change their cropping system to minimize soil washing and how to manage their fields so that the topsoil can be built up instead of destroyed. Different departments of the College of Agriculture, University of Illinois are cooperating.

The McLean county project, spread out over an area of 14,000 acres, is one of 20 which the Department of Interior is undertaking in different parts of the country to cope with the menace of soil erosion. At least 100 million acres of formerly cultivated land, an area as large as the state of Illinois and much of it originally good land, have been practically destroyed by erosion. Another 100 million acres of crop land are in serious danger. More than 400 million tons of suspended solid matter and many more millions of tons of dissolved matter pass out of the mouth of the Mississippi river every year.

-M-

### Illinois Second Among 20 States In Corn-Hog Sign-Up

Illinois ranks second among the 20 states that have signed up the first 800,000 contracts in the government's corn-hog adjustment program, according to reports which the extension service of the College of Agriculture, University of Illinois has received from Agricultural Adjustment Administration headquarters at Washington. The Illinois total is more than 110,000.

The sign-up to date is regarded by leaders of the campaign as encouraging evidence that a large proportion of the corn and hog production both of the state and the nation will be covered by AAA contracts when the sign-up is completed. This, of course, means definite progress in adjusting corn and hog production to effective demand and thereby rebuilding the farmer's purchasing power, it was pointed out. Iowa, conceded to be the largest producer of both commodities, is first with a count of 155,000 contract applications, according to the latest figures available.

-M-

### Best Vegetable Varieties Tested For Illinois Gardens

Every season adds a few more new varieties of vegetables available to Illinois gardeners, and 1934 is no exception, says B. L. Weaver, of the horticultural department at the College of Agriculture, University of Illinois.

This ever-increasing list of varieties is often confusing to the urban gardener, and even more so to the farmer or home gardener, unless it is realized that many of the new names mean only a slight change in size, shape, color, texture, flavor, season or productivity, points out Weaver.

After many tests under varying conditions, the experiment station at the College of Agriculture, University of Illinois has singled out a number of varieties found to be most applicable to Illinois conditions and which can be recommended to most growers. These varieties include:

Asparagus - Mary Washington.

Green snap bush beans - Stringless Green Pod and Round Pod.

Yellow bush beans - Fenwick Pod Black Wax and Round Pod Kidney Wax.

Pole beans - Kentucky Wonder.

Bush lima beans - Henderson's, Fordhook and Pompee.

Beets - Early Wonder for early planting, Lutz Greenleaf for late, and Detroit Dark Red for canning.

Cabbage - Golden Acre and Copenhagen for early, if Bursarium wilt disease is not present in soil, and Jersey Queen, Marion Market and Wisconsin All-Seasons for later harvest.

Carrots - Nantes Coreless, Chantenay and Red Core Chantenay.

Sweet corn - Howling Mob for mid-season; Evergreen, Golden Cross Bantam and Top Cross Bantam for late. Early varieties are not recommended owing to prevalence of Stewart's disease.

Lettuce - Black-Seeded Simpson and Prizehead for leaf. New York and Mignonette for head varieties.

Mushrooms - Lake Champlain for early; Male's Best, Bender's Surprise, Top Top, Honey Rock and Hearts of Gold for main crop; Ohio Sugar for green flesh variety.

Radishes - Scarlet Globe and Saxa for early; Crimson Giant White Icicle and Cincinnati Market for late spring; White Strasburg for summer.

-M-

### Some 23 Common Crops Serve As Hosts For Chinch Bugs

Some 23 different grasses will aid the chinch bug in its destructive march across Illinois this spring and summer unless farmers take steps against what threatens to be one of the worst infestations in the past half century, says C. M. Woodworth, chief in plant genetics at the College of Agriculture, University of Illinois.

It has been found, however, that the chinch bug does not relish legumes such as alfalfa, sweet clover, soybeans and other clovers. Thus planting these crops so as to separate the fields of small grains, corn and grasses is suggested as one of several control measures.

So far as small grains are concerned, explains Woodworth, barley, spring wheat, winter wheat, rye and oats are preferred by the insect in early spring. The second brood, which comes along in June and July, feeds mainly on corn and the sorghums, including broomcorn, kafir corn and Sudan grass. Other crops on which the chinch bug can exist, in the absence of small grains and corn, are millet, timothy, barnyard grass, tickle grass, crabgrass, foxtail and other wild and cultivated grasses. Kentucky bluegrass does not seem to be attractive to the bugs, and only a few are usually found feeding on it.

## Illinois Dairymen Give Views On Adjustment Program

Views and suggestions of dairymen and agricultural leaders in Illinois, fifth leading dairy state, with regard to the proposed program of the Agricultural Adjustment Administration for the adjustment of the dairy industry are a matter of record, following a regional meeting at Indianapolis on April 2 and 3. Indiana, Ohio, Michigan and Kentucky, in addition to Illinois, were represented at the meeting.

No definite action for or against the program was taken at the meeting, the idea being merely to get the views and suggestions of farmers and dairy leaders. Sentiment of producers at 14 similar meetings to be held in different parts of the country will determine the administration's next step on the dairy problem. The meetings will not be concluded until the middle of the month.

The official Illinois representatives attending the Indianapolis meeting were Dean H. W. Mumford, of the College of Agriculture, University of Illinois; H. A. Fische, head of the dairy department; C. S. Rhode, dairy extension specialist; J. C. Sittler, state leader of farm advisers, and E. J. Keilholz, extension editor.

Details of the proposed plan were presented by A. H. Lauterbach, chief of the dairy section of the Agricultural Adjustment Administration; G. M. Reed, associate agricultural economist of the administration, and A. B. Nyström, senior dairy husbandman of the U. S. Department of Agriculture.

Standards in the dairy industry problem as it was outlined at the Indianapolis meeting are these facts: a volume of milk production which increased by two billion pounds from 1930 to 1932; a cow population of more than 25 million, which is larger than it has ever been before; an average price index of 69 as compared with 140 in 1929, and a total cash income from milk sales which dropped from \$1,847,000,000 in 1929 to \$385,000,000 in 1932.

The proposed program would involve benefit payments totaling not less than 150 million dollars to dairy farmers who reduced their milk sales by between 10 and 20 per cent of their average annual sales for 1932 and 1933. Illinois dairymen would be eligible for a maximum of \$7,155,000. The method of reduction would be left to the individual farmers. Furthermore, it would not be expected to reduce sales below the low winter level, but to cut down about 10 per cent from the first average volume of the 1932-33 base period.

The plan also includes allocation of additional funds for purchasing and distributing milk among underfed city children, for purchasing and distributing healthy cows to needy farmers to produce milk for their own families and for speeding up the eradication of bovine tuberculosis and Bang's disease.

Sound methods of cropping, cow feeding and herd management whereby individual dairymen who sign contracts could control their production were outlined at the Indianapolis session.

The proposed program would be financed by a processing tax starting at 1 cent a pound of butterfat and gradually advancing to 5 cents a pound as supply came under control. There would be a compensatory tax on oleomargarine sufficient to prevent shifts to this product as a substitute for butter.

### Erosion Damage On Illinois Soils Shown By Gullies

Eight hundred gully checks of different kinds which the soil erosion service of the U. S. Department of Interior has already built in McLean county stand as monuments to the speed and certainty with which soil erosion already has cut into the fertile lands of Illinois, it is pointed out by F. A. Fisher, Illinois regional director of the service.

The 800 gully checks which have been built as part of the demonstration to show farmers how to cope with the menace of soil erosion range all the way from small 4-foot wire checks to the large 5-foot, multiple-post checks. Some of them are imposing looking, rock-dam structures.

Building of gully checks is a sort of last-line defense against the inroads of erosion. The checks are not built at the mouth of the gullies, because in many instances erosion has cut so deeply that it will take too long or be impracticable to try to fill in the gullies. Instead, the checks are built at the head of the gullies as a means of preventing them from eating back any farther into the farm. The gullies then are reclaimed by being seeded to permanent pasture crops or planted to trees.

While the gully checks are a striking feature of the demonstrational work that is being done in the McLean county area, they are only a part of what will be done to show farmers how to hold their land in place by means of mechanical devices of various kinds, by proper cropping systems and by sound farm management methods. Fisher, who has his offices at the College of Agriculture, University of Illinois and who has the cooperation of the college in his work, already has operations well under way in the McLean county demonstrational area.

Erosion, against which the demonstration is directed, is eating away in some form or other at approximately half the 80,000,000 acres of Illinois far land, Fisher said. For the United States as a whole, the cost of erosion to farmers is estimated at \$400,000,000 a year, and it is washing the soil off fields of the United States at the rate of three billion tons a year, he added.

### Illinois Farmer May Be Oldest Of Corn-Hog Packer

Joseph J. Ford, 112-year-old farmer of Crawford county, is believed to be the oldest producer in Illinois, if not the United States, to sign up in the AAA corn-hog adjustment program, according to the extension service of the College of Agriculture, University of Illinois.

Inasmuch as 115,000 farmers in Illinois have signed corn-hog contract applications, according to the latest reports, and more than 1,000,000 producers throughout the nation are cooperating in the AAA campaign, Ford's friends claim that he is "one man in a million."

Ford owns 115 acres of land near Flat Rock and recently signed a corn-hog contract application in which he agrees to reduce his 1934 corn acreage at least 10 per cent and his hog production 15 per cent, under the terms of the government-led adjustment program.

He says that he expects to see the next corn crop harvested and he invited the members of the local corn-hog committee to his next birthday party.

Although Crawford is not considered a prominent corn and hog producing county, Farm Adviser Harold Allison reports that more than 60 farmers have signed with the county's oldest entity in the corn-hog adjustment movement.

-X-

Rotation Changes May Control Damage From Chinch Bugs

Threatened with the heaviest chinch bug infestation ever recorded in the history of the state, Illinois farmers should consider revising their rotations as a means of partially protecting their 1934 corn crop, warns A. L. Lang, assistant chief of soil experiment fields, College of Agriculture, University of Illinois.

By this is meant the location of legume crops in the rotation so as to isolate the small grain, corn and grass fields where the chinch bugs are prone to breed and feed. It has been proved that legumes are distasteful to this insect pest, and separating the bug's "favorite" crops with legumes is suggested as one of several control measures. Furthermore, the addition of one or more legumes will improve the fertility of the land on which they are grown.

"A five-year rotation supplying this dual purpose," explains Lang, "may consist of corn, oats, clover, corn and soybeans. In this case, not only is 60 per cent of the farm in legumes, but 80 per cent is in cash crops. One crop of corn is completely set off between two legumes, which in many cases will prevent serious damage from chinch bugs. The fact that the oats field will have a spring seeding of clover may deter rapid multiplication of the insects in this crop, if the clover gets a strong, early start.

"When wheat is grown with a mixture of corn, a rotation of corn, corn soybeans, wheat and clover can be planned. An important feature of this combination is that the small grain crop, which is always the early breeding ground of the chinch bug, is isolated from the corn crops by a legume on either side. With a good, growthy spring seeding of clover in the wheat, this crop is not susceptible to the bugs.

"Where a four-year rotation of corn, oats, wheat and clover is followed, a protective revision would be to substitute soybeans for the oats. This would carry the isolation advantages of the previously mentioned wheat rotation and, with a good stand of clover in the wheat, would keep 75 per cent of the land in legumes throughout the growing season."

-M-

AAA Dairy Plans Creating Interest In Herd Testing

Anticipating the coming of the government's dairy adjustment program, when definite milk and butterfat production records will be of added value, more and more Illinois farmers are forming dairy herd improvement associations so that the profitability of their cows may be checked every month, says J. G. Cash, dairy extension specialist of the College of Agriculture, University of Illinois.

This rapid growth of interest in dairy testing work is revealed in the fact that within the past two months new associations have been organized in Lake, Lee and Iroquois counties, while several other associations have added new members. With these new additions, approximately 1,100 Illinois dairymen now belong to 57 associations in which some 20,000 cows are tested regularly.

## AAA Program Might Mean \$158 To An Illinois Dairyman

Benefits of as much as \$158 a year could be counted on by a typical north central Illinois dairyman if he signed up under the proposed dairy production adjustment program of the Agricultural Adjustment Administration, according to figures given by the extension service of the College of Agriculture, University of Illinois. The figures hold for conditions as they are now and do not take into account the effect of the proposed processing tax upon consumption, it was pointed out.

What is considered more important is the fact that by signing up, the dairyman would have joined with his neighbors in safeguarding the dairy industry against the effect of ruinously low prices which threaten to come about as a result of the excessive potential producing possibilities of the country's dairy herds and the low buying power of the consuming public.

The dairyman in the typical case cited by the college keeps around 14 cows producing 7,600 pounds of milk a year. He feeds each cow approximately 2,234 pounds of grain a year, and 589 pounds of this feed must be bought.

Without signing up he would be producing 108,700 pounds of milk a year. Under the basic-surplus plan on which this dairyman and others like him now operate, 87,000 pounds of this milk would be sold as basic milk at \$1.50 a hundred pounds, bringing a total of \$1,305. The remaining 21,700 pounds would be sold as surplus at the rate of \$1 a hundred pounds and would bring \$217. The total income from the sale of milk would be \$1,522. The 8,400 pounds of feed which this dairyman must buy costs him \$1.50 a hundred pounds, or a total of \$126. When this is subtracted from his sales receipts, it leaves him a net return of \$1,396.

His net returns would be \$158 more than this if he signed up to reduce 15 per cent and if there was a two-thirds sign-up of all dairy farmers with a 10 per cent reduction in dairy sales for the country as a whole.

By signing up to reduce 15 per cent, he would get benefit payments of \$1.50 a hundredweight for the 16,300 pounds of milk that he cut off his sales. This would be a total of \$245. He would still get \$1.50 a hundred pounds or a total of \$1,305 for his 87,000 pounds of basic milk. In addition he would still have 9,400 pounds of surplus milk for which he would get \$1 a hundredweight or a total of \$94. This would give him a total of \$1,604 from sales and benefit payments.

He would make his required 15 per cent reduction in sales by buying and feeding 60 per cent less feed concentrates than he bought and fed before signing up. In other words, his bill for purchased feed would be only \$50. This would leave him a net return of \$1,554, or \$158 more than he was getting before signing up.

-M-

With final reports still to be received from 14 counties the number of corn-hog contracts that have been signed up by Illinois farmers stood at 121,043 on Tuesday, April 10, it was announced by Prof. J. C. Spittler, state leader of farm advisers, who is representing the extension service of the College of Agriculture, University of Illinois in the AAA campaign.

-M-

### U. I. Tests Suggest Pasture Mixtures for AAA Acres

More Illinois land will be seeded to grass during the next two years than ever before in the history of the state, prophesies H. P. Rusk, head of the animal husbandry department of the College of Agriculture, University of Illinois.

This "back-to-grass" movement is spreading throughout the state as a result of the government's corn-hog and wheat adjustment programs in which some 2,000,000 acres of land will be taken out of crop production by cooperating Illinois farmers.

"A large percentage of this former wheat and corn land," explains Rusk, "will be seeded to permanent or semi-permanent pastures for livestock, and many Illinois producers are wondering what grass seeds or mixtures of seeds should be used.

"For early livestock carrying capacity of permanent pastures, all records at the University of Illinois were broken by a heavy seeding consisting of 12.3 pounds of bluegrass, 2.5 of red clover, 2.5 pounds of sweet clover, 4.1 pounds of timothy, 1.6 pounds of alsike clover and .4 pounds of white clover. This mixture may be used for seeding contracted acres, without violation of the AAA corn-hog contract, provided it is in addition to the average acreage devoted to pasture in 1932 and 1933 and is not pastured in 1934.

"If it is desired to pasture this seeding lightly this fall, sweet clover must be replaced in the mixture. This can be done by increasing the amount of the other legume seeds, or by substituting 2 to 5 pounds of alfalfa. Furthermore, the mixture must be seeded without a nurse crop if it is to be pastured this fall.

"Several other factors, in addition to a good seed mixture, should be considered in developing a permanent pasture. They include the use of relatively clean land of high fertility; preparation of a good seed bed, heavy seeding of bluegrass and legumes; control of weeds by frequent clipping during the first season; allowing grass to get a good start in spring before cattle are turned on, and grazing heavily but not too long for any one period."

-M-

### Feeding Cows Yeast Will Enrich Milk With Vitamin D

Adults may not have to go to the sunny beaches nor children take their daily dose of fish oil to acquire their vitamin D in the future, according to J. M. Brannon, assistant chief of dairy bacteriology at the College of Agriculture, University of Illinois. "Old Bossy," when fed especially-treated yeast as a part of her daily ration, will supply this bone-building vitamin in her milk, it is said. Heretofore the most common methods of securing vitamin D for the human system have been to expose the skin to direct sunlight or to ultra-violet ray machines or by consuming certain fish oils.

"Normal milk contains calcium and phosphorus in the proper ratio for the development of bone tissue in children, but it is low in vitamin D and does not have a large supply of the substance which is converted into vitamin D," explains Brannon. "Investigators, however, have found that certain types of yeast are high in the substance from which vitamin D is made, and if these strains of yeast are treated with ultra-violet rays of light, they become excellent sources of vitamin D. Likewise if yeast so treated is fed to cows their milk at the end of three weeks will contain sufficient vitamin D to insure the proper development of the bones of a child."

Production of this special bone-building milk entails additional costs. Dairymen selling it must secure a license costing a dollar a cow. There is also the extra expense of purchasing the treated yeast.

-M-

"Importing" Chinch-Bug Corn May Not Be Safest Plan

Illinois farmers, casting about for a variety of seed corn that will be most resistant to chinch bug attack in 1934, will do well to select the variety that is the best adapted, most vigorous growing and highest yielding in their respective areas, rather than import a variety said to be resistant in another part of the state or in another state.

This is the opinion of G. H. Dungan, assistant chief of crop production at the College of Agriculture, University of Illinois, after reviewing experimental evidence and the experience of farmers relative to chinch bug resistant varieties of corn.

"There is evidence that some strains of corn are less favored by chinch bugs than others," explains Dungan, "but the particular quality which makes them less appetizing to the bugs is not known. It is believed, however, that the most important factor is the superior vigor which enables the plant to produce a good crop of corn in addition to supporting a goodly number of bugs. No plant during its vegetative growth can withstand an attack by an unlimited number of chinch bugs but the ability of a variety to remain green and continue growing until the normal maturity date, in spite of the insects, is a mark of resistance.

"In southern Illinois, where varieties have been tested at the college's Alhambra experiment field, Champion White Pearl, Black Hawk, Mohawk and Golden Beauty have proved to be the best adapted to the upland soils, and at the same time the most resistant to chinch bugs. Waddell Utility White Dent supplies a good type of grain for feeding and seems to be resistant to the bugs, although it does not stand up as well under a severe infestation as does Champion White Pearl.

"Experimental evidence is not available covering the most chinch-bug-resistant varieties of corn in central and northern Illinois and positive recommendations can not be made. However, farmers in the north-central section of the state last year reported that the corn known as Krug is markedly resistant. In the absence of thorough experimental tests on the resistance of varieties grown in northern and central portions of the state, it is suggested that the best adapted, most vigorous growing and highest-yielding varieties be grown in these sections during years of chinch bug outbreaks."

-M-

Effingham Eggs Are Among First To Carry U. S. Seal

The first shipments of eggs from an Illinois egg-buying station, under official government grading, have been inaugurated in Effingham county, with the Farmers' Equity Union there adopting U. S. standards for packing and shipping to the New York market, according to H. H. Alp, poultry extension specialist of the College of Agriculture, University of Illinois.

Through the cooperation of the U. S. Department of Agriculture and the Illinois Department of Agriculture, officers of the union have been able to secure the services of a licensed government grader and permission to use the government seals on various grades of egg packs. The grading is in line with work which the extension service of the agricultural college has been carrying on throughout the state to raise the quality and the value of the Illinois egg crop.

"During the four years from 1929 to 1932 the cash income of Illinois farmers from eggs has averaged \$20,240,000 annually, but the opportunities to sell those eggs on a graded basis have been all too few," Alp said. "With the proper cooperation of the members and the right kind of management, such a program as that started in Effingham county should do much to raise the quality and price of eggs produced in that area."

## Record Alfalfa Seeding Forecast On Illinois Farms

A new all-time record for alfalfa growing is expected to be set in Illinois this year in spite of the fact that the 1933 crop of 1,710,000 acres was a record in itself, according to J. C. Hackleman, assistant superintendent of the College of Agriculture, University of Illinois. He said that the 1,710,000 acres of Illinois land that will be reseeded this year will gain 100,000 acres for the various adjustment programs which will be at once available in place for starting an alfalfa meadow while at the same time obtaining some income from the crop in the form of benefit rental payments, he pointed out. Alfalfa may be seeded in May with or without a nurse crop, he said.

Use of contracted land for alfalfa and other crops is explained in a new circular, No. 420, "How Use Contracted Acres," which the college has just issued for free distribution to interested farmers. Hackleman is joint author with O. M. Linsley, soils extension specialist.

Record plantings of alfalfa are only one indication of the extent to which Illinois farmers are carrying out the college's long-time teaching for the growing of more legumes on Illinois farms, Hackleman said. This has been advocated for years not only as a means of adjusting production to demand but also of reducing production costs, of conserving land resources as a continuing source of wealth and of controlling insects and diseases.

As most of our growing season is needed to establish a good alfalfa field, there is no better place to start than on the contracted acres. However, alfalfa should be seeded only where the soil is known to be sweet enough to produce the crop and where soil tests indicate that there is sufficient available phosphorus to make production of the crop relatively safe.

If the alfalfa is to be seeded with a nurse crop, oats probably should be used in most parts of the state since this crop is far less attractive to crickets than is barley. Barley near a cornfield would be a worse hazard to the crop than would oats. Oats used as a nurse crop for alfalfa should be clipped before they head out. If the oats grow too fast, they probably should be clipped twice so that no large amount of material will be left on the young alfalfa at any one time and thus endanger the stand.

Alfalfa may also be seeded alone in May, after a thorough preparation of the seed bed, if weeds have been kept under control for several years on the land. Such seeding will likely require two or three clippings during the year. The final clipping should be made about the middle of August.

No hay can be taken from alfalfa seeded on the contracted acres during 1934. The hay can, of course, be used in 1935 if the contracted acres have been released.

If summer seeding of alfalfa is preferred, the ground can be plowed and thoroughly prepared this spring. The seed bed should be worked at frequent intervals thus insuring the killing of several crops of weeds. Seeding should be done in late July or early August so that the crop will be ready for use as hay in 1935. Any contracted wheat acreage to be seeded must be replaced by an equivalent contract of acreage in 1935.

Chinch Bugs Going to Small Grains; Farmers Warned

Chinch bugs, worse than they have been for years, have started flying from their winter quarters to small grain fields, and the cheapest and most effective way for farmers to fight them from now on is through the use of crops that are immune to attack, it is pointed out by the College of Agriculture, University of Illinois in a new circular, "Fighting the Chinch Bug on Illinois Farms."

The bugs are even worse now than they were one year when farmers in 17 southwestern Illinois counties lost practically  $6\frac{1}{2}$  million dollars as a result of damage to corn, wheat and oats alone, not counting injury to other crops and secondary losses, the college says.

Especially this year, when farmers are reducing their corn acreages under the adjustment program, control of the bugs may mean the difference between a farmer's raising enough feed for his own needs and for sale or else having to buy practically all of his feed, it is pointed out.

Six direct and indirect methods of fighting the bugs are outlined in the new circular by W. P. Flint, chief entomologist of the Illinois Natural History Survey and of the agricultural experiment station; G. H. Dungan, associate chief in crop production at the agricultural college, and J. H. Bigger, assistant entomologist of the natural history survey.

Of all the methods, the cheapest and most effective is the use of chinch-bug proof crops, the circular says. These include such crops as alfalfa, red clover, sweet clover, alsike clover, lespedeza, cowpeas, soybeans, sunflowers, flax, sugar beets, artichokes, potatoes and rape.

During the rest of April and throughout May and June, the chinch bugs and their newly hatched young will be found in fields of small grain or tender, succulent grasses. The flight from winter quarters to the small grain fields takes place throughout this period. The real damage threatens to begin about the middle of June and afterward, when the bugs of the first brood migrate on foot from the small grain fields to corn. Once in the corn they soon acquire wings and scatter over the entire field.

Farmers desiring the help of the new circular in fighting chinch bugs on their farms can get copies from their county farm advisers or from the College of Agriculture, University of Illinois at Urbana.

Export Trend Has Little To Cheer Illinois Farmers

Possibilities of restoring the income of Illinois farmers through a revival of foreign markets are none the brighter on the basis of export figures which the College of Agriculture, University of Illinois has just received from the bureau of agricultural economics, U. S. Department of Agriculture.

Showing a further decline, the index of the volume of farm products exports from the United States was 80 for February of this year as against 93 for January, 109 for December and 71 for February of last year. The index for February, 1952, was 117. The average of 1909-1914 is taken as 100 in the index figures.

The decline recorded in the figures brings home the importance of the state-wide agricultural adjustment program which the college started in 1928 under the direction of Dean Herbert W. Mumford and has been carrying on ever since, it was pointed out. More recently the loss of export markets and its attendant problems have been attacked in the AAA activities now being sponsored by the U. S. Department of Agriculture.

-M-

Proper Rotation Of Crops Will Aid Chinch-Bug Fight

Proper rotation of the \$182,000,000 worth of crops that they grow annually is one of a half dozen hopes for Illinois farmers, now that chinch bugs are on the move in what threatens to be the worst infestation of these destructive pests that the state has had for years, it is pointed out by the College of Agriculture, University of Illinois and Illinois Natural History Survey.

Crop rotation is a safeguard because a good way to hold the insect in check is to make its food scarce somewhere along the line, it was explained. Bugs of the first brood, which mature in the small grain during the late spring, depend for their food mainly on wheat, oats, barley and rye. The second brood, which matures in the corn during the summer, feeds almost exclusively on corn.

"This means that wheat-growing areas should cut down on their acreages of corn, substituting if possible some crop on which the chinch bug will not feed, so as to reduce damage from the first brood bugs that will come out of the wheat. Heavy corn-producing areas should reduce the acreage of small grains so that the first brood will be starved out, thereby reducing the size of the second brood.

"A rotation of corn, soybeans, wheat and clover will suffer as little loss as any rotation that contains both wheat and corn.

"In an area where wheat is the main money crop, a rotation of 25 per cent wheat, 25 per cent soybeans or cowpeas, 25 per cent wheat with some oats or rye and 25 per cent red or sweet clover will be satisfactory because it contains no crop on which the second brood of chinch bugs can feed.

"Where corn is the main money crop, a rotation of 40 per cent corn, 20 per cent soybeans, 20 per cent wheat or oats and 20 per cent red clover, sweet clover or alfalfa may be used.

"The essential point in arranging a rotation to prevent chinch bug injury is to grow as large an acreage as possible of the crops on which the insect does not feed. Where both small grains and corn are grown on the same or on adjoining farms, the fields of these two crops should preferably not adjoin."

Crop rotation and other methods of fighting the chinch bug are explained in a new circular, No. 419, which county farm advisers and the extension service of the College of Agriculture, University of Illinois have available for interested farmers.

-M-

Times To Harvest Asparagus Shown By U. of I. Tests

Asparagus, which ranks as one of the leading truck crops of Illinois with a total value of more than half a million dollars in 1930, should not be cut severely until the second year after the plantation is set, and in some cases not until the third year, according to a seven-year experiment conducted by the College of Agriculture, University of Illinois. The results are reported by E. P. Lewis, in a new bulletin, "Asparagus Yields as Affected by Severity of Cutting."

-M-

Changing Rose And Carnation Soils Is Needless Work

Time and labor spent in changing greenhouse soil each year for the production of carnations and roses is neither necessary nor economical, if the old soil can be sterilized and kept in a high state of fertility, according to experiments conducted by F. F. Weinard, and S. W. Decker, of the College of Agriculture, University of Illinois. Their results are reported in a new bulletin, "Experiments on the Use of Old Soil in Growing Carnations and Roses."

## Ferocious AAA Dairy Program Is Dropped For Present

A limited program of diseased cattle eradication and relief purchases of dairy products financed by funds made available by congress, coupled with the continued use of milk marketing agreements, will probably be the extent of any dairy program which is authorized by the Agricultural Adjustment Administration.

For the present at least no benefit payment dairy production control program will be undertaken.

This decision of AAA officials in Washington was announced in a telegram received by Dean Herbert W. Mumford, of the College of Agriculture, University of Illinois, from D. W. Warburton, director of the extension service in the U. S. Department of Agriculture.

The decision followed a study of reports from the AAA regional dairy conferences and is in accord with the fixed policy of the administration not to attempt adjustment programs without the expressed consent of a substantial majority of the producers concerned.

Although abandoning for any time being the idea of a benefit payment program, the AAA will continue its study of dairy problems and will be prepared to initiate a program which may seem sound if it appears that the dairy industry as a whole is agreed on such a program, the telegram to Dean Mumford said.

With the immediate future of the dairy program settled, representatives of every group concerned with the beef cattle industry met in Chicago on Thursday April 6, to analyze their difficulties and to see what might be done under the Agricultural Adjustment Act for the benefit of beef producers.

## U. of I. Students Take Sweepstakes In Flower Show

A record of having won the sweepstakes trophy two years in succession in the collegiate exhibits classes of the National Flower and Garden Show is now held by floricultural students of the College of Agriculture, University of Illinois following the recent show in Rochester, N. Y.

Production of such exhibits is part of the training which the students are receiving for places in the floricultural industry, which in Illinois is producing products having an annual value of approximately seven million dollars, according to the last census.

Entries made by the Illinois students, competing with those from Cornell, Purdue, Michigan State College, Rutgers and Penn State, won seven first and eight second prizes, or more than any other school represented in the show. Purdue was second in total number of prizes and Cornell, third.

Seventeen of the 27 awards were won by the Illinois students at the St. Louis, Mo., show last year, when they took the sweepstakes prize.

More than 167 pots of floral plants and vases of cut flowers were entered this year from Illinois, 11 of which had been grown by students as part of their class and laboratory work beginning last September.

Illinois Sign-Up In Corn-Hog Rearing Campaign

With the last of the reports coming in, indications now are that the total sign-up of Illinois contracts in the government's corn-hog rearing campaign may reach 123,100, it is announced by Dean Herbert W. Mumford, of the College of Agriculture, University of Illinois and chairman of the state advisory committee.

This does not represent the total number of farms that are under contract, because in some cases two or more farms are covered by one signature, it was explained. Farmers signing up have agreed to reduce their corn production 10 per cent and their hog farrowings and marketing 10 per cent in 1944.

How soon the 100 million dollars of the rebates in benefit payments will start coming to farmers who are reducing will depend upon how soon the contracts are submitted to Washington. Farmers, themselves, members of county allotment committees and other workers in the campaign are now putting the finishing corrections and alterations on the contracts, preparatory to sending them to Washington.

The first agreements to reach the Washington AAA offices for approval and issuance of benefit payments came from Marion county, Ia. It is expected that the peak of agreements will come during May. Machinery and personnel for approving the agreements and issuing the benefit payment checks are being organized. The checks are expected to be written within about two weeks after the agreements start through the contract records section for approval and payment. The maximum daily capacity is about 45,000 checks a day.

In Illinois, the heaviest reductions will be made and the largest benefits collected in 16 counties with 1,700 or more contracts signed up. Heading the list is McLean county with 1,761 contracts, and then follows Iroquois with 1,100, Livingston 1,064, LaSalle 1,000, Champaign 941, Vermilion 834, Bureau 790, Shelby 740, Henry 646, Fulton 600, Knox 567, Macoupin 511, Whiteside 464, Sangamon 460 and Lee 404.

-M-

Heavy Rainfall At Right Time Would Check Chinch Bug

Only in the case of frequent, heavy rains during the latter part of May and June can the weather be counted upon to aid Illinois farmers in their battle against what threatens to be one of the worst invasions of chinch bugs in years, warns W. P. Flint, chief entomologist of the Illinois Natural History Survey and entomologist of the College of Agriculture, University of Illinois.

Unfortunately, the chances are three to one that May and June will be comparatively dry months, he said. He suggests, therefore, that farmers be prepared to use barriers and traps when chinch-bug migration from small grain to corn fields begins in June. Planting the most resistant varieties of crops and seeding legumes in as many fields as the rotation system will permit are other safeguards that can be used.

Heavy rains in the early spring may have little or no effect on the bugs, but frequent rains during the last half of May and June will reduce infestations. Even in the worst chinch bug years, such rains will keep down the insects to the point where no serious damage will occur.

"The rain beats the young bugs down into the ground and 'buries' them in so they die. Also dampness and high humidity are favorable to the spread of the white fungous disease which attacks the insects.

"Likewise, if a period of very wet weather occurs in August, starting about the first and continuing throughout the month, the second brood of chinch bugs will be greatly reduced. Usually this means no damage the following year."

-M-

Best Not To Raise Hogs At All If Pastures Not Clean

If a farmer can not get his young pigs out on clean pasture and practice other sanitary measures, he will be better off by not raising any hogs, in the opinion of the Division of Animal Pathology at the College of Agriculture, University of Illinois, when referring to the close relationship between health and profit in swine production.

"Necrotic enteritis, sore mouth, lung worms, round worms, thorn-headed worms, whip worms and stomach worms, all of which are filth-borne diseases and parasites, are some of the major causes of stunting, unthriftiness and unprofitable pigs, it is pointed out. When pigs are raised in the same lot year after year the ground becomes saturated with the disease germs and eggs of the parasites passed out in the manure. The young pigs rise then on either directly or by eating bugs which have consumed the eggs, and in a short time are infested in great degree unthriftiness and they die.

"Clean soil is also necessary in the prevention of anemia, for from the soil the pigs obtain certain elements needed for blood building," explains Dr. Thom. "If the pigs can not be taken to the clean soil, then the soil should be brought to them."

If the pigs are not crowded in brooder houses in clean, new pastures, they should be housed (not driven) to one place no hogs have run for at least a year. Preferably this field should be one that has been cultivated since last used by hogs. Of course, the field should be well cleaned and the pigs should not get back into the barnyard of former hog lots where they may become infested and lose the benefit of having been taken to new pasture.

Experience has shown that pigs raised in short crops on contaminated lots or pastures until four months old are usually unthrifty and can be marketed at an earlier age with a lower feed cost and at a higher price.

-11-

Factors Indicate Brighter Outlook For Poultry Raisers

Four important factors indicate that Illinois poultrymen may find themselves in a more favorable position financially during the coming months than they were at the same time last year, says H. H. Aly, poultry extension specialist of the College of Agriculture, University of Illinois.

Egg prices have had the habit of going into the "doldrums" during the late spring and early summer during the last two years, explains Aly. "Whether this year they will reach the low of 1933 remains to be seen, but there are some indications that they will not.

"Storage holdings of shell eggs, generally considered to have a distinct bearing on the fresh egg market, contain a note of improvement. On March 24 of this year there were in storage in 16 cities a total of 473,000 cases of eggs as compared with 524,000 on the same date in 1933. This is a decrease of 10 percent and the movement of eggs into storage is reported to be slower than the five-year average.

"Last fall there were many flocks of pullets housed that were below normal in development and vigor. Consequently production has been unsteady and this has resulted in many hens being culled. Thus there is some question as to whether the spring flush of production will reach its usual volume of past years.

"To date the prevailing egg prices have encouraged rather free selling which has resulted in a fairly good consumer demand being established. Eventually egg prices should reflect any general increase in factory wages, provided there is not too rapid an increase in prices of other things the wage earners can buy."

## Million Illinois Cattle Figure In Beef Adjustments

More than a million cattle marketed annually by Illinois farmers would be affected by whatever plans the proposed committee of 25 feeders and breeders works out for a national beef cattle adjustment program, according to the College of Agriculture, University of Illinois.

That such a committee be appointed by the Agricultural Adjustment Administration to investigate the possibilities of a beef adjustment program and make tentative plans to be submitted to farmers was recommended in action taken by representatives of the beef industry who attended the recent AAA meeting in Chicago. Approximately 700 cattlemen from 24 states attended the meeting, with Illinois being the most heavily represented.

The key to the beef cattle problem, as it is seen by AAA officials at Washington and as it was presented at the Chicago meeting, is the elimination of from six million to seven million cows and heifers on farms. As an initial effort, two million head of cows, in addition to usual marketings, might be removed in 1934 through eradication of diseased animals and through relief purchases. Contracts with individual producers might be required to assure that any removal program adopted would not be offset by further increases in breeding and feeding.

Beef cattle prices not only followed the decline in other farm prices during the depression, but continued to drop until in 1933 they were \$2.05 a hundredweight less than the parity price. In March of this year they were \$2.46 a hundredweight below parity.

"There may be a temporary improvement in beef cattle prices in 1934 partly because of smaller receipts in well finished, corn fed cattle, caused by the shortage in the 1933 corn crop, and partly because of the continued pick-up in consumer buying power," the AAA officials pointed out at the Chicago meeting. "However, maximum returns to cattlemen will depend upon sound and prompt adjustments in cattle numbers.

"From 1928 to 1934 numbers of all cattle--beef and dairy--in the United States increased from about 57,000,000 head to about 67,000,000 head. Milk cow numbers increased by about 22 per cent and beef cows by about the same percentage.

"Annual cattle slaughter may be expected to rise from about 21,000,000 head a year to about 24,000,000 head in the next several years, unless prompt action is taken, although the number of finished cattle coming to the market has not yet begun to reflect fully the increase in the number of breeding stock."

"During each of the past six years cattlemen have produced from 1,000,000 to 1,500,000 more cattle than they have marketed. That is, they have been adding to their herds faster than they have been selling off. Thus a new cattle production cycle has been under way for six years, and we still are definitely on the upward trend in numbers of cattle.

-M-

### Inferior Seed To Be Avoided In Increasing Soybeans

In order to plant an additional 114,000 acres of soybeans this year, Illinois farmers should not yield to the temptation of using cracked, old, or otherwise inferior seed, if they hope to secure satisfactory stands, warns C. A. Van Doren, assistant in crop production at the College of Agriculture, University of Illinois.

Last year Illinois farmers planted and harvested the smallest crop since 1929, and with an anticipated increase of 20 per cent in acreage this year, some growers may be tempted to be less critical of the quality of seed they plant, it is said.

Reports of planting intentions indicate that Illinois farmers will seed about 682,000 acres this spring as compared with 568,000 acres last year and 617,000 acres in 1932. The 1931 crop of 771,000 acres was the largest in the history of the state. Normally Illinois growers harvest more than half the soybeans produced in the United States.

Experiments at the U.I. College of Agriculture show that cracked soybean seed will produce only 55.4 per cent as heavy a stand as sound seed, although the difference in ultimate seed yields is not as pronounced.

The age of the seed should also be considered, if maximum production is to be attained, explains Van Doren. New, sound seed is always preferable, since one-year-old seed usually falls 2 per cent short in stand as compared with new seed that has been stored under average farm conditions. In some cases, however, the one-year-old seed may produce as large or a larger yield than the newseed, all other factors being comparable. It is seldom advisable to plant soybeans that are two years old or older, as both the stand and yield decline rapidly from the second year on.

"Good quality soybeans consist of seed that was well matured and in a dry condition when harvested, and has been stored under favorable conditions," points out Van Doren. "Seed harvested from frost-killed plants or from plants cut before completely matured, are likely to be inferior. Furthermore, changes in atmospheric humidity make the beans deteriorate in storage. If a farmer must purchase his seed, he should buy new, sound-appearing beans that will give a germination test of at least 90 per cent strong sprouts."

-M-

### Nuts Are Suggested As Non-Surplus Crop For Illinois

High quality nuts constitute one of the few crops in which there is not a surplus, and many Illinois farmers could well afford to devote a small acreage to their production, declares R. S. Marsh, horticultural extension specialist of the College of Agriculture, University of Illinois. To assist farmers in doing this he is holding a series of nut propagation demonstrations in 14 Illinois counties within the next week or two.

At the nut propagation demonstrations, Marsh and L. E. Sawyer, extension forester of the Illinois Natural History Survey and of the U.I. College of Agriculture, will explain the latest method of top working walnut, pecan and hickory trees. Farmers attending will be given an opportunity to make a graft so that they will have a model to take home with them, together with complete printed instructions.

Local arrangements for the demonstrations are being made through the county farm advisers, with tentative dates scheduled as follows:

Union and Jackson counties, May 8; Pulaski-Alexander and Saline counties, May 9; Johnson and White counties, May 10; Williamson and Edwards counties, May 11; Schuyler county, May 14; Stark county, May 15; Bureau county, May 16; and Jo Daviess county, May 17.

-M-

### Fruit Bud Loss In Illinois Than In Eastern States

Illinois peach growers fared better than those of the eastern states insofar as damage to orchards as a result of sub-zero weather during the past winter is concerned, it is reported by Dr. M. J. Dorsey, chief in pomology at the College of Agriculture, University of Illinois.

Although there was severe injury to the peach buds in this state, no damage was done to the trees. In fact in some of the more favored locations, sufficient buds survived to produce small crops of varying percentages. In the east, however, all fruit buds were killed by the freezing temperatures, and a great many trees were killed or damaged badly, it is said.

The Illinois peach crop has been estimated at about 800 carloads, as compared with approximately 2,000 cars in the bumper season of 1931. As was anticipated the apple crop is likely to be light in this state, owing to the defoliation and unfavorable weather during fruit bud formation last year. Red raspberries suffered considerably from winter kill, but the cherry and plum buds are believed to have survived comparatively well. Unfortunately in some parts of the state cold nights during the last week or ten days of April did considerable damage to certain fruit blossoms.

Differences in bud hardiness were illustrated strikingly this winter in Illinois, Dorsey points out. Such peach varieties as Greensboro, South Haven, Carmen and Bell came through the winter in a much better shape than the more popular Elberta and J. H. Hale. This would indicate that for home plantings it might be advisable to include more of the hardier varieties. These would give more assurance of a crop in some seasons when the other varieties have been winter damaged.

In orchards where the live buds are too few to be worth considering, Dorsey suggests that growers prune the trees back to the two or even three-year-old wood. In cases where there are sufficient live buds to give a crop, pruning should be delayed until the set is evident, after which the non-bearing branches can be thinned out.

Where the bud survival is still lighter, it is advisable to leave all possible bearing wood in the trees so that full advantage can be taken of the live buds. Here, too, an application of some form of quickly available nitrogen should be made in order to increase the set. This is particularly worthwhile, if applications were not made last year or if the growth conditions are at a low ebb.

-4-

### Too Much Hulled Oats Will Hinder Fattening Pigs

In their efforts to grow and fatten fall pigs as cheaply as possible Illinois farmers are sound in their practice of not including too large a proportion of hulled oats in their rations, it is revealed in a two-year feeding experiment just completed at the College of Agriculture, University of Illinois. Hogs fed on a dry lot on hulled oats as the only grain developed severe stiffness, became lethargic and in one case died.

The addition of hulled oats, however, did improve the so-called standard ration of corn and protein supplement, according to W. E. Carroll and W. F. Garrigus, who conducted the tests. The most satisfactory ration was found to be one in which the pigs consumed two parts cracked corn, one part hulled oats, plus .26 pounds of protein supplement and .12 pounds of minerals daily. These pigs consumed 44 pounds of the ration for each 100 pounds of gain and increased in weight at the rate of 1.45 pounds daily. The protein supplement was made up of 2 parts tankage, 1 part soybean oil meal and 1 part alfalfa meal, while the mineral mixture consisted of equal parts of limestone, bone meal and salt.

## 3,000,000 Acres Of AAI Land In Hot Planting Period

Leaving approximately two million acres out of our total production, Illinois farmers will do under terms of the government's various AAI programs, is not going to upset sound farming methods or bring about any radical changes in cropping systems, judging from reports coming to the farm management division of the College of Agriculture, University of Illinois. Quite the contrary, the contracted land is going to be used almost entirely for legumes. This is directly in line with the long-continued tradition of the college and will pave the way for soil conservation, the reduction of production and marketing costs, better control of insects and diseases and other benefits.

How far Illinois farmers have gone in this direction in the past 25 years is shown by the fact that during the five-year period of 1929-1933 the average annual acreage of such legumes as alfalfa, sweet clover, soybeans and cowpeas was 1,418,000 acres more than it was in the five-year period of 1911-1915. Furthermore the average annual acreage of such surplus crops as corn and wheat, together with oats, rye and buckwheat, was 1,561,000 acres less in Illinois during the 1929-1933 period than it was during the 1911-1915 period.

Extensive use which farmers are now making of the state will make of legumes on their contracted acreage is indicated in figures reported by J. B. Cunniff, field man for the farm business-farm management service, which the U. I. College of Agriculture sponsors in Grundy, I.S. 11-, Marshall and Putnam counties. The figures cover 82 farms on which 116 pieces of land have been contracted to the government.

Alfalfa or sweet clover will be used on 68 of the tracts; red, mammoth or clover on 24 of them; timothy or orchard grass on 1 of them, and soybeans for plowing under on 4 of them. Thirteen of the tracts will be allowed to kill weeds and on five others nothing will be planted and the weeds clipped. Owners of two pieces of the land are undecided how they will handle the contracted acres.

Forty-two farmers are leaving old clover, alfalfa or grass mixtures stand over as their contracted acres, thereby saving labor and expense this year. However, most farmers are not prepared to do this, for out of the 116 pieces of contracted land, 64 were in corn last year.

In seeding such corn land down as contracted acres, about 30 per cent of the farmers abandoned the usual practice of using a nurse crop, thereby eliminating a place for the chinch bugs to feed and also saving expense.

While the percentage of contracted land growing legumes on these farms is exceedingly high--perhaps much higher than on farms not in the farm management service--it would probably be still higher were it not for the large amount of sour soil, Cunningham reported. This is being partly corrected on ten of the farms where some of the agricultural adjustment benefit money is being used to buy limestone. The four farmers who plan to sow soybeans on their contracted acres are doing so because of sour soil. Others have sown mammoth clover, which stands a medium acid soil.

Wheat Prospect Below Average; Carryover Also Lower

Although it is anticipated that the 1934 wheat crop in Illinois may be larger than the unusually small crop of last year, it is likely to be some 2,000,000 bushels less than the five-year average production of the state, according to available reports reviewed by R. C. Ross, assistant chief of farm management at the College of Agriculture, University of Illinois.

The total 1934 wheat yield in Illinois has been estimated at 29,691,000 bushels, as compared with 26,592,000 bushels in 1933 and 31,311,000 bushels as the average during the five years of 1927-1931. The increased wheat acreage planted last fall was probably the result of the large amount of corn land that remained idle last summer. Rather than lose the time and labor they had spent in preparing the ground for corn, farmers planted the fallow acres to wheat, in the opinion of Ross.

Wheat stocks on Illinois farms as of April 1 amounted to 2,839,700 bushels, or the smallest carryover since 1921. Last year at this time wheat stored on Illinois farms totalled 5,245,000 bushels.

Current reports on the world wheat prospects indicate the carryover of wheat on July 1 in the four principal exporting countries will be at least 12,000,000 bushels less than on July 1 of last year.

Like that of Illinois, the North American wheat crop is expected to be considerably larger this year than last, because of the exceptional hard growing conditions of last year, but the European crop may be considerably smaller. Dry weather in the lower Danube basin has delayed late-sown grain, and early-sown fields may have yields reduced even though the moisture has been sufficient for a favorable early development of the crop.

The condition of winter wheat in the remainder of Europe is reported as being generally good except in Italy and Spain. However, the early-season condition of the crop in the more humid parts of Europe has not proved to be a good indication of subsequent yield. It is not likely that the high average yields of last year will be repeated in 1934.

-15-

Increased Soybean Acreage Will Yield Many Benefits

Illinois farmers, who this year plan to plant approximately 262,000 acres of soybeans, will be in a position to reap many advantages from the crop, particularly in the case of producers who are cooperating in the government's wheat and corn-hog adjustment programs, in the opinion of E. E. DeTark, chief of soil technology at the College of Agriculture, University of Illinois. At least six characteristics of the crop can be cited as advantages.

When plowed under, soybeans add nitrogen to the soil in much the same manner as other legume crops. Then too, this crop has the ability to absorb mineral plant food elements which are ordinarily not readily available, and when the soybeans are turned under, the minerals become easily available for the following crops.

Experiments have shown that the tops of soybeans, when plowed down help the development of bacteria, thereby making the soil more favorable for future crop growth. Furthermore, soybeans need less lime or limestone than the more commonly grown clovers. Although not the most ideal crop for soil erosion prevention, soybeans give quick results in producing a protective cover, and when broadcast or drilled around a slope will do much in holding the soil. Finally, soybeans are distasteful to chinch bugs, and if the contracted acres are located between the small grain and corn fields, this legume tends to discourage the bugs from migrating from the small grain to the corn field where they do the greatest damage.

Although soybeans fit in ideally as a green manure crop for contracted acres, they are not used as such in general farm operations, being less practical for soil improvement than certain other legumes.

-16-

### Cutworms Threaten Success of Spring Insect and Cole

If Illinois should have cold, wet weather soon after corn sowing, farmers may expect another cutworm invasion and should be prepared to control the insects with poisoned bait, says J. H. Bigler, assistant entomologist of the Illinois Natural History Survey in a report to the College of Agriculture, University of Illinois.

After the cutworms have become established in a field, the use of poisoned bran bait is the only control method available, points out Bigler. This should be used as soon as signs of cutworm feeding appear.

Enough poisoned bait for about three acres can be made with 25 pounds of low-grade bran, 1 pound of Paris green or sodium arsenite or white arsenic, 2 quarts of molasses and 3 gallons of water. For larger areas, proportionately larger amounts will be required.

The water, molasses and either arsenite or arsenic are mixed together and then the solution is stirred into the bran so that every particle of the bran is moistened by it. Just enough of the solution should be used so that the mixture will hold together when squeezed tightly in the hand but will crumble when spread. A little experience will establish this point.

If Paris green is used instead of sodium arsenite or white arsenic, it should be mixed dry with the bran, and the water-molasses solution poured over this mixture until it is sufficiently wet.

The bait should be spread late in the afternoon so that it will retain moist conditions. Broadcasting by hand or with a machine should be at the rate of 5 to 10 pounds to the acre, given sufficient wind to circulate heavy dustation.

In the case of black cutworms, often found in dense, wet sections and particularly in wet years, one application of the poisoned bait will not be enough. Repeated applications are necessary.

-14-

### Characteristic View Is Held By Growers Of Strawberries

Illinois strawberry growers, whose crop has averaged more than a half billion dollars annually in recent years, are optimistic about the present because of the earlier crop which is in market and more money in circulation, says E. S. Marsh, extension specialist in horticulture at the College of Agriculture, University of Illinois. Whether or not they get the maximum returns will depend partly upon how carefully they grade their berries and the extent to which they use shipping point inspection service, he said.

"What can be done through grading and shipping point inspection to get better prices for strawberries is shown in the results obtained last year by a new growers' cooperative organized in Edgar county. Its members received a higher net return than the members of any other organization either in Illinois or Indiana. Principles of grading, packing and marketing were taught to them in five demonstrations held by the extension service of the U. I. College of Agriculture with the cooperation of the State Division of Standardization and Markets.

"Better marketing methods also paid a premium for growers in Union county, where pan grading was introduced by the U. I. agricultural extension service. As a result of several demonstrations held by the farm adviser, the average price received throughout the season was \$1 more a crate where pan grading was used than where no grading was done. The extra cost of pan grading, including the value of the cull berries thrown out and the expense of extra labor, amounted to 25 cents a crate. This, however, left an extra net profit of 75 cents for the growers who employed the pan-grading method."

## Home Accounts Show Increased Buying By Farm Families

That Illinois farm families are contributing their share to improved business and industrial conditions is revealed in a survey of 215 farm and small town home account records made by Mrs. Ruth C. Freeman, home economics extension specialist of the College of Agriculture, University of Illinois.

Comparing the 167 farm family records studied in 1933-34 with 159 summarized in 1932-33, it was found that the total average money value of living and savings was  $5\frac{1}{2}$  per cent higher during the last 12 months than in the 1932-33 period. The increase occurred in cash expenditures, probably resulting from increased incomes of the farmers in one form or another.

The total realized income of the 42 small town families, however, was 11 per cent lower in 1933-34 than during the previous 12 months.

Cash house expenditures by the farm families, including cash repairs, fire insurance and improvements on houses, nearly doubled in 1933-34 over 1932-33, points out Mrs. Freeman. They ranged from nothing to \$324, or an average of \$12 to the family.

Forty-four per cent of the 167 farm families purchased paint and varnish for decorating interior walls and floors in the past year. 42 per cent repainted one or more rooms, and three farm houses were painted.

Expenditures for furnishings and equipment in 1933-34 were also nearly double that spent in 1932-33. Twenty large pieces of electrical equipment were bought in the past year, as well as 13 mattresses, 14 rugs and 3 complete suites of furniture. Small kitchen equipment, curtains and draperies, dishes, toweling, chests and pillow cases, and oil cloth were among the most frequent purchases shown in the records.

Clothing expenditures in 1933-34 averaged \$161 as compared to \$91 in 1932-33, with from one-fifth to one-third of each person's clothing money going for shoes and hose.

Automobile expenditures of the 167 farm families also increased in 1933-34, although the difference was not large. Eight families traded in their old cars for new ones, and eight others traded for late model used cars. The 159 families in 1932-33 bought only three new cars.

Seventy per cent of the farm families attended the World's Fair in Chicago last summer, considering the trip both educational and recreational, and entering the expenses accordingly in their books.

Even with increased expenses, the farm families were able to save an average of \$148 each, the major portion of which was in the form of life insurance premiums.

Further heartening signs are seen by home economics extension workers of the college in the recent almost record growth of county home bureaus and the livelier interest which farm women are showing in new ideas on home making and home management. A total of 1,469 new members have enrolled in Illinois home bureaus during the past five months, making the total membership now stand at 9,341. Twenty-six community home bureau units have been organized in the state since December 1, 1933.

### Cow Culling Sets Stage For State Efficiency Record

Elimination of thousands of low producing and unprofitable cows by members of Illinois' 53 dairy herd improvement associations made it possible for their herds to set a new state record in efficiency of production during the past year, according to a report by Prof. C. S. Rhode, chief of dairy husbandry at the College of Agriculture, University of Illinois.

The 20,048 cows retained by the herd improvement association members averaged 321 pounds of butterfat each during the past year. This is the highest efficiency record ever attained by association members in Illinois and is 141 pounds better than the 180-pound butterfat average of all cows in the state. In 1932 the average butterfat production for cows in dairy herd improvement associations in this state was 317.6 pounds as compared with 315.1 pounds in 1930 and 322.4 pounds in 1931.

Members of herd improvement associations have realized more than ever during the past three years that the practice of culling inferior and better cows is a sound method of adjusting their individual problems, as well as the problems of the industry as a whole, it was explained. Consequently during these three years, many Illinois association dairymen have practiced rigid culling, disposing of approximately 10,000 low-producing cows.

How efficiency of production actually affects the producer is shown by the estimated return of \$76.72 above feed cost for the average cow in this state, while the average cow in dairy herd improvement work returned \$64.31, or an increase of more than 14 per cent.

In point of individual production, a grade Holstein cow owned by the Roseheart Home in Kane county led all others of the state with a record of 4,254 pounds of milk containing 1,570.3 pounds of butterfat. The highest-producing herd in the state in 1933 was owned by Tirm and Rabston, of Boone county, with an average of 574 pounds of fat and 14,671 pounds of milk.

### Chinese Cabbage May End State's Sauerkraut Problem

A new delicacy may be served to the 45,370 inmates in Illinois' 27 charitable and penal institutions and a big problem in the diet and feeding of these people may be solved if experiments started by Leo A. Somers, vegetable production attention specialist of the College of Agriculture, University of Illinois, prove as successful as they promise to be.

The new delicacy is sauerkraut made from Chinese cabbage instead of the common cabbage, which sometimes fails under fall weather conditions in Illinois. A. L. Bowen, director of the Illinois State Department of Public Welfare, and other state officials already have sampled the new kind of sauerkraut. Some of them pronounced it superior to common cabbage sauerkraut, some said they could tell no difference and others did not like it as well. It has been more or less common opinion that sauerkraut could not be made from Chinese cabbage, or "celery cabbage," as it is sometimes incorrectly called.

Sauerkraut is a mainstay in the diets that are served at the state's 27 charitable and penal institutions. Unfortunately, however, the fall crop of cabbage which must be relied upon for the kraut is frequently a failure in this state. Chinese cabbage, being strictly a fall crop and much easier to grow than common cabbage, would overcome the danger of a crop failure, but the question was whether or not kraut could be made from it. Somers tried it out on a small scale last fall and successfully produced a satisfactory kraut. As a result of the success of the preliminary experiments, each of the state institutions will be asked to grow a batch of Chinese cabbage kraut this fall.

-M-

Good Horses Rare on the Farm Is Generally Realized

Although it has been known that the number of work animals on farms in the United States has been declining as much as 50,000 horses and mules in a single year, the scarcity of good work stock in Illinois is even more pronounced than generally realized, according to W. Crawford, associate in animal husbandry of the College of Agriculture, University of Illinois.

The number of horses, mules and colts on farms in this State as of January 1 of this year totalled approximately 24,000 as compared with 25,000 on the same date in 1920, or a decline of 1,000 head in two months. The population of horses, mules and colts in Illinois in 1920 was 24,000, in 1921 it was 23,000 and in 1922 totalled 22,000.

Farmers have sold down to their minimum needs and will seldom price a horse for sale, says Crawford, following a typical enough central Illinois ranch which he made a survey of the available funds.

"There are a few teams of unimproved which can be bought and a few bits of rather plain order," he explains. "Of course, after the cross are in, there will be some horses which can be used."

"Quite a few farmers are in need of more horses and are in the market for teams of mares. Of late, farmers' ideas have changed radically in respect to the use of horses. They now insist upon buying good animals, and their own indications of a return of greater pride in horses and better care given them."

"Stallion owners are still, as usual, in business to they can handle. Likewise, there are quite a few deals to be seen in the markets. Yet when one considers that it takes four or five years to produce a work horse, as well as the high proportion of old horses on farms, there is little likelihood of too many being raised in the near future. The main difficulty will be in the scarcity of young mares and stallions."

-1-

Incubator Run After Eggs Leave Farm Lowers Quality

Complaints of consumers about the low quality of eggs sometimes offered for sale during summer months can often be traced to careless management on the part of people handling the eggs after they leave the farm, says H. H. Aly, poultry extension specialist at the College of Agriculture, University of Illinois.

Poor quality eggs tend to reduce purchases by housewives, and this in turn lowers the prices and profits received by both farmers and dealers. Thus with the approach of warm weather, greater care should be taken in handling eggs as a truly perishable product, it is said.

Too often, eggs are held in the back room of a store which also serves as storage space for various items, some of which should never be in the same room with eggs. This room during the summer months will frequently have a temperature high enough to start the incubation of fertile eggs. Another criticism in this connection is that often the small country buying stations do not have satisfactory places to hold a product as perishable as eggs.

In one instance last summer, when the prevailing temperature was about 90 degrees Fahrenheit, Aly reports visiting a produce house consisting of a large room covered by a sheet metal roof. In this room poultry was being fed and eggs stored until time for delivery to the next buyer. "Regardless of how good the quality of these eggs when originally received by this dealer, they would quickly deteriorate under such conditions," he explains.

## Breath-Maker, Chinch-Bug Barrier, Must Be Made Early

Favored by the continued dry weather, chinch bugs are becoming so numerous that they will soon be making short work of the corn in some of our farms. It is best to take steps immediately to establish a barrier against their progress, according to a warning by W. P. Flint, chief entomologist at the Illinois State Natural History Survey and of the College of Agriculture, University of Illinois.

Hordes of the pests will soon be leaving fields of harvested small grain to continue the destruction of corn, and only the prompt building of a barrier to their progress will prevent a serious loss to be incurred. As soon as the chinch bugs draw, Flint said.

These barriers can be made by running a furrow around the field, throwing the dirt toward the corn and then spreading this ridge, which should be 6 to 8 inches high. The furrow should be worked down with a hand implement that it will make a smooth, dusty surface.

After this has been done, post holes 12 inches apart should be dug along the ridge side of the furrow about 15 feet apart. The tops of the holes should be filled and kept dusty so that the dirt will fall into them as they migrate along the side of the furrow seeking a meal.

As soon as the chinch bugs begin migrating from the small grain to the corn fields, a liquid repellent should be applied to the top of the ridge. Various repellents (not the expensive wood preservative type of kauri-oil, naphthalene drain oil and to some extent pine tar oils are the most effective repellents because of their strong, disagreeable odor. Ordinary road oil and used crank case oil do not have sufficiently repellent odor and are not worth the labor of application.

A handy container for carrying the crude kerosene or other repellent material can be made by punching an L-shaped nail hole in the side of a metal bucket about an inch from the bottom and directly below the point where the handle is attached. A stream of kerosene or naphthalene oil flowing from such a hole will form a liquid barrier ridge wide enough to turn back the bugs.

The repellent material should be renewed between 1:30 and 3:00 o'clock each afternoon for the first several days, and then every other afternoon during the 14- to 16-day period when the bug migration is active. Bugs trapped in the post holes should be destroyed each afternoon about sundown by pouring one or two table spoonsful of kerosene into each hole, scattering it over the bugs. The kerosene should not be ignited.

Between 25 and 50 gallons of the repellent solution will be sufficient to maintain a quarter-mile barrier during the danger period, and the usual cost is about 15 cents a gallon. An acre of corn saved will usually more than pay for the maintenance of a barrier one-fourth mile long.

Plans are being made for demonstrations in approximately 50 inhabited counties to teach local leaders proper methods of constructing and maintaining chinch-bug barriers. These local leaders, in turn, will push the building of barriers in their own communities.

Illinois Dairyman Looks To Sires For Higher Returns

Illinois dairymen who are planning for the time when the market demand will be for milk and butterfat but secure higher returns through the use of "fancy and better" cows, are looking especially to their herd sires. For example, this in dairy husbandry at the College of Agriculture, University of Illinois. During the past year alone at least 20 dairy bulls of important grade of the state have been "proved" on the basis of definite production records on their daughters, he reported.

That the herd sire of today has a definite influence on the dairy returns of tomorrow is shown by the fact that daughters of 13 of the 20 sired bulls showed an average increase in milk production over their dams, while 11 showed a decrease. The daughters of 14 of the sires produced more butterfat than their dams, but the daughters of 11 produced less.

Continued use of a sire whose daughters produced less than their dams will gradually destroy the profitability of a herd, while the use of well-proved bulls gradually increases the efficiency of a herd, he explained. How this theory can actually take place is illustrated in the case of the bull, One King Took.

One King Took was once rated as seven-cubbed but later was shown to be a better butterfat producer than his dam. From this situation seven daughters were dropped which eventually produced an average of 100 pounds of butterfat. Thus these daughters averaged 100 pounds of fat more than their dams, or an increase of 4 per cent in butterfat annually.

A study of the pedigree of this bull reveals that he did not have a record for this high production. His sire had an advance register designation of high average production, and his dam had a high record. The sire was mated by a good bull and out of a high-producing dam. The dam of this bull also had three high-achieving daughters, thus proving that she could transmit high production. Such a lineage records by which the value of a sire may be judged, however, are available only through regular testing in a dairy herd improvement association or advanced registry facilities.

Many Illinois dairymen have improved the production level of their herds through good feeding and close culling, and if further improvement is to be made, much of it must come through the use of bulls capable of siring cows with higher levels of production, it is said.

Highly Girls Set High Goal For 4-H Club Work In 1937

Illinois boys and girls now enrolling in 4-H clubs throughout the 15 counties of the state, are starting to begin their 1937 activities, having a high goal set for them in the accomplishments of those who took part in such club activities last year, according to figures released by the extension service of the College of Agriculture, University of Illinois.

Of a total of 25,111 farm youngsters, ranging in ages from 7 to 18 years, who are carried on definite projects under direction of the agricultural college, 15,000 are county fair and home advisers. Assisted by 1,771 local club leaders, 11,400 members of the girls and 21.6 per cent of the boys completed their projects last year. Of the members enrolled last year had taken part in 1936 club activities in three or more previous years. Many were carrying on club work for their fifth and sixth consecutive years.

The value of the livestock produced and cared for by Illinois 4-Hers last year amounted to approximately \$70,000,000, while the gross value of the products of \$77,000,000, reports H. I. Dillmore, extension specialist in agricultural club work at the U. I. College of Agriculture. Enrollment in agricultural club work last year at 11,400 girls, explains Mary A. Mink, extension specialist in rural home work.

-4-

Sowing Soybeans And Corns May Help Meet Feed Need

Threatened with a serious feed shortage as a result of the dry weather and the chinch bug menace, Illinois livestock farmers still have a chance to meet the situation by planting additional loads of soybeans or cowpeas for hay, according to the animal husbandry department, College of Agriculture, University of Illinois.

Dry weather since the early part of April has retarded the growth of pastures, meadows and small grains. At the same time the abnormally dry season has been particularly favorable for the reproduction of hordes of chinch bugs, the most destructive and widespread insect pest present in the state. Much of the hay being made general in a short time, therefore, contains very little nutritious matter of livestock feed, it was predicted.

Since chinch bugs do not feed on legumes, it is being suggested that Illinois farmers take heed to start to increase their soybean and cowpea acreage for hay production. It may be advisable to plant rows of the grain crop in the rows of these crops.

Both soybeans and cowpeas are excellent roughage crops for stock, dairy and broiler stock. When these crops are fed to the animals in a well-balanced ration, they greatly improve the palatability of the feed. In fact, they are being planted in the central and northern portions of the state and south of the Ohio River in Illinois.

Soybeans are usually sown in rows 30 inches apart in a thoroughly prepared seedbed which should contain sufficient moisture to germinate the beans. Inoculation is, of course, recommended. Two or three bushels with a grain drill, 5 to 7 rows of beans will be required to the acre, or if planted in rows 15 to 20 inches apart, 35 to 45 pounds will suffice in the case of medium-sized seed.

Sudan grass has also given satisfactory results as a hot weather pasture and hay crop in Illinois. However, since sudan is one of the favorite foods of chinch bugs, it will be advisable to seed either soybeans or cowpeas as a companion crop to sudan grass this year. Using 1 bushel of beans or 2 or 3 pounds of sudan grass to the acre gives a practical seeding.

-M-

Food Costs Total One-Fifth Of Rural Family Expenditures

Although farmers in this state produce 64 per cent of the food served on their tables, the grocery bill is still the largest item in the family's cash expenditures, according to a survey of 187 home account records made by Mrs. Ruth C. Freeman, home economics extension specialist of the College of Agriculture, University of Illinois.

During the past year the Illinois farm families covered in the survey made total cash expenditures ranging from \$155 to \$1,774, or an average of \$575 each, points out Mrs. Freeman. Of this amount, \$147, or 25.4 per cent went for the purchase of food.

Cash operating expenses such as telephone, fuel, light and power, ice, servant hire, soap, matches and similar small supplies amounted to 14 per cent of all cash expenditures. Another 14 per cent, or approximately \$81 for each family, was used in buying clothing.

Automobile charges accounted for the fourth largest item, involving 11 per cent of all cash expenditures, while recreation and education activities required 11 per cent, or an average of \$77 for the average family during the year.

## Will Grain Be in Demand for Feeding in the Future?

When we consider the fact that the grain which we produce in our own country will have to be sold to other countries, and that the grain which we buy from other countries will have to be sold to other countries, it is not surprising that we should be interested in the question of the demand for grain in the future.

The demand for grain in the future will depend upon many factors, but in most cases it will be determined by the amount of grain which is produced in the world.

The demand for grain in the future will also depend upon the amount of grain which is consumed in the world. Although the young population of the world is increasing rapidly, the amount of grain which is consumed in the world is not increasing as rapidly as the population. This is because the amount of grain which is consumed in the world is determined by the amount of grain which is produced in the world.

The demand for grain in the future will also depend upon the amount of grain which is stored in the world. The amount of grain which is stored in the world is determined by the amount of grain which is produced in the world and the amount of grain which is consumed in the world.

The demand for grain in the future will also depend upon the amount of grain which is used for other purposes. The amount of grain which is used for other purposes is determined by the amount of grain which is produced in the world and the amount of grain which is consumed in the world.

The demand for grain in the future will also depend upon the amount of grain which is used for other purposes. The amount of grain which is used for other purposes is determined by the amount of grain which is produced in the world and the amount of grain which is consumed in the world.

The demand for grain in the future will also depend upon the amount of grain which is used for other purposes. The amount of grain which is used for other purposes is determined by the amount of grain which is produced in the world and the amount of grain which is consumed in the world.

Dr. Woodford has invited a number of dairymen and other dairymen in approximately 15 different counties are planning to visit the College of Agriculture, University of Illinois, this summer for the purpose of studying approved methods of feeding, breeding and management as demonstrated in the Agricultural College Herds. Woodford and his dairymen were the first to visit the trial.

-12-

Why During the Last Year Garden Irrigation Failed

They have the idea of arranging their garden beds have been scoffed at by Illinois farmers, but the unusually dry weather of this spring has brought home the possible value of irrigation in a convincing way, says F. A. Jensen, vegetable gardening extension specialist at the College of Agriculture, University of Illinois. Not all Illinois farms, but a very large number, then might have irrigated gardens at small expense, he said.

During drought seasons a simple, homemade watering system can make the difference between a productive garden and a total loss. Likewise, having sufficient water at the proper time is particularly important to late-planted vegetables.

In a majority of cases the Illinois farmer's garden is built on a slight elevation with the water laid out on a wide, short distance from the source of water. Generally, too, the water is pumped powered by a windmill or gasoline engine that is capable of supplying more water than is needed for household and livestock consumption.

Although it is possible to lay a pipe, explaining Jensen, a main line of pipe running from the live water to the garden to the generally shallow garden, a long piece of hose that can be rolled in and out to rows is needed. If the water source is below the upper level of the garden, the pipe can be laid directly to the pump and the water forced up to the level of the garden.

By using a hose, a satisfactory irrigation system can be laid out between the rows of vegetables. The end of the hose can be connected to the upper end of a narrow channel that is rolled to the garden to the pump. As the narrow hose is rolled, the hose can be drawn out of the garden. It will be necessary, of course, to keep the channel open and to maintain the water supply, but in most cases the system is simple and does not require constant attention.

Different types will, naturally, require different adaptations of any type of watering system, for the problem is far from a simple individual one. However, if Illinois farmers will look over their own situation, a great many will find it entirely possible and practical to irrigate the garden with but little expense and labor.

41-

Rival Teams Will Give Their Chance in Pulling Match

Who owns the best pulling team of horses in Illinois? Will Willard Rueds, of Springfield, be able to lose the state championship? What factors should be considered in the selection of good pullers?

These are some of the questions that are going to be decided in the annual series of horse-pulling contests to be conducted in different parts of the state by the College of Agriculture, University of Illinois. E. F. Robbins, livestock extension specialist, will be in charge.

Four contests have already been scheduled for this summer and fall, and others may be arranged before the season gets under way, it is said. The first is to take place at the Illinois State Fair, Springfield, on August 1 and 2. The first day teams weighing less than 3,000 pounds will compete, with the heavier teams testing their strength the following day.

Champaign county horsemen are planning to compete with each other at a Joseph on August 12, while those of Warren county will stage their horse-pulling contest on August 31. The first contest scheduled this year for outside Illinois will be held at Sandwich, in DeKalb county, on September 5.

Emergency Hay And Pasture Are Now Hope Of Farmers

Hay and pasture crops for the \$19,415,000 worth of livestock on Illinois farms have been burned out to one of the lowest levels in the world, and only emergency plantings will save the situation for many farmers, according to J. J. Fisher, associate chief of crop production at the College of Agriculture, University of Illinois. Experiments conducted for a number of years by the agricultural staff of the college stand farmers in good stead in showing how to produce severely needed forage in times like these, he said.

Sudan grass, soybeans, cowpeas, millet and sorghum may yet be planted for the purpose of furnishing either hay or hay during late summer and early fall. Under favorable weather conditions, they are usually ready for grazing within six weeks after a sowing, and may be planted as late as the first part of August with reasonable confidence of a crop of hay or pasture before the first frost. Planting, however, should not be delayed until it is almost impossible to insure germination of the seed after planting, it is said.

Because sudan grass is one of the favorite feeds of chinch bugs, the crop should not be grown where the pest is in the extreme northern and southern ends of the state. In most Illinois counties, sudan grass should be grown in combination with either soybeans or cowpeas, which are distasteful to chinch bugs. Planted at the rate of 15 pounds of seed an acre and 1 to 2 bushels of soybeans or cowpeas, the combination may be expected to give satisfactory results.

If the farmer desires, he may substitute either German or late Wender millet in the place of sudan grass, but the quality of the hay and the hay of a less desirable quality in the case of millet. In the planting of the crop relative to the chinch bug, it should be planted in combination with either soybeans or cowpeas at practically the same rate as sudan grass.

When the farmer has access to grain sorghum seed which may be needed instead of the sudan grass crop, a combination with soybeans or cowpeas. However, if he must purchase seed, it is more practical to buy sudan grass rather than millet or sorghum seed.

In pasture plantings, sudan grass or sorghum are seeded, the fields should not be grazed after the first frost owing to the danger of a serious and poisoning the livestock. Although it is believed that prussic acid does not develop in pure sudan grass, so much of the seed available has been accidentally crossed with sorghum that grazing after frost may result in prussic acid poisoning.

Carbondale To Be Site Of Guernsey Field Day, June 7

Celebrating the rapid growth in popularity of Guernsey cattle in this state, Guernsey breeders and their friends from southern Illinois will gather at Coll. Grove farm, near Carbondale, June 7, for a special field day and picnic.

Between 400 and 500 dairymen and their families are expected to attend the event which is being sponsored by the Illinois Guernsey Breeders' Association. J. R. McNeil, of Tuscola, president, and H. J. Farnham, of Danville, secretary of the state organization, will be in charge of the field day.

At present there are more than 5,000 purebred Guernsey cattle on Illinois farms, or an increase of approximately 120 per cent since 1920.

C. S. Ficks, chief in dairy husbandry at the College of Agriculture, University of Illinois, will appear on the field day program to discuss dairy and breeding problems in Illinois, with special reference to the purebred Guernsey and the Guernsey breeders.

## Clinch Bugs Unharmd By Light Rains; Barriers Urged

Except where there have been heavy rains, the record hordes of chinch bugs have not been thinned out by recent rainfall, and barriers therefore are still the one hope of farmers in protecting their young corn against the first-brood bugs, according to W. P. Flint, chief entomologist of the Illinois State Natural History Survey and of the College of Agriculture, University of Illinois.

It is not too late to build barriers against the bugs even after they first get into the corn, Flint said. However, in such cases it is necessary to go out into the corn, beyond the line which the bugs have already reached, and build the barriers there with the idea of saving as much corn as possible. Corn back of the barrier, where the bugs are feeding, should then be destroyed to force the nests into the barriers.

There has been some question about the merit of barriers from farmers who have felt that the bugs were so thick and so far advanced that it was futile to attempt stopping them, Flint said.

Thousands of miles of barriers have been built as a result of demonstrations which have been staged by county farm advisers, the extension service of the College of Agriculture, University of Illinois and the Illinois State Natural History Survey, cooperating. Farm Adviser H. A. deWarr, of Woodford county, for instance, estimated that 100 miles of barriers were built to protect Woodford county corn fields last year and that an estimated 1,000 miles of barriers would be needed in that county alone this year. The 100 miles of barriers built last year took a cash outlay of \$3,000 but they saved corn that was worth \$90,000 at present prices, Farm Adviser deWarr pointed out.

Throwing up barriers will protect corn against the first-brood bugs marching from fields of destroyed barley, oats, wheat and rye to continue their destructive feeding in nearby corn fields. Later on the second-brood bugs may destroy corn of poor stand on weak ground, even though it is protected by barriers, but these second-brood bugs will not begin appearing until about the middle of July. Furthermore, if there are good rains in July and August, bugs of the second brood will be drowned out or "mudded" in, and the damage from them will be reduced.

Total damage from the pests undoubtedly will run into the millions, and anything that can be done to save some corn may be profitable, Flint pointed out. One year the bugs caused an estimated loss of 6½ million dollars to farmers in 17 southwestern counties alone, and this year they are worse than ever before and are scattered over 70 counties, he said. Aided by the drouth, the record number of bugs now present in the state are destroying fields of wheat, rye, oats and barley and are moving to corn fields in search of food a month earlier than usual.

"If the weather remains dry and it seems that the cost of a creosote barrier is not justified, a dust barrier, may be used. However, such barriers are effective only while the soil is dry and must be dragged several times each afternoon to remain effective."

Planting Of Emergency Crops Pushed To Supply Feed

Thousands of acres of Illinois land where small grains, pastures and meadows have been ruined by drouth and chinch bugs are now being planted to soybeans and other substitute crops just as fast as sufficient rain comes to permit planting. Legumes like soybeans and cowpeas are being used most extensively because they are resistant to chinch-bug attack and can still be planted at these late dates. Crop specialists of the College of Agriculture, University of Illinois reported that most Illinois farmers had laid in their supplies of soybean seed and were only waiting for sufficient rain.

Seeding of a crop like soybeans is not considered safe until after enough rain has fallen to connect with the sub-soil moisture, crops specialists of the college pointed out.

While soybeans and cowpeas will be the most popular emergency crops, sudan grass, millet and sorghum will also be used by some farmers. However, these latter three crops are good prey for chinch bugs, and it therefore is recommended that they be seeded in combination with soybeans or cowpeas. The combination may be seeded at the rate of 10 pounds of sudan grass, millet or sorghum and 3 to 1 bushels of soybeans or cowpeas.

Possibilities for Illinois farmers to produce at least part of their needed feed through the growing of emergency and substitute crops have been increased through the lifting of restrictions in the AAA corn-hog and wheat contracts. All the thousands of AAA contracted land in the state, as well as any and all non-contracted acreage, can now be turned to the production of certain hay, forage and pasture crops to offset the feed shortage resulting from the unprecedented drouth.

Farmers who have signed corn-hog and wheat contracts are now making the most of the new ruling which permits them to use their contracted acres for all hay, pasture or forage purposes, except the planting of fodder corn and grain sorghum.

Heretofore the use of contracted acres has been so limited that contract signers were only permitted to pasture additional permanent pasture that was seeded without a nurse crop.

The modification is particularly helpful to farmers who are now short of pasture or hay and who last spring seeded their contracted acreage to a forage crop with the intention of plowing it under for soil improvement. This crop may now be cut for hay or pastured as the contract signer desires.

The new ruling also helps farmers who get aside for their contracted acres old bluegrass or clover pastures which they intended to plow under in a soil improvement program. This acreage can now be pastured or used for hay.

Furthermore, the contracted acres can now be planted to soybeans, sudan grass or millet to be used as an emergency pasture or forage crop in late summer and early fall. Such crops, however, must not be cut for seed purposes but must be fed as forage. Farmers can, however, sell hay from these acres to a neighbor who has no hay.

In addition, the limitations have been modified to the extent that any and all non-contracted acres may be seeded to any crop for forage purposes, including fodder corn and grain sorghum. Heretofore, farmers were limited in their plantings of these crops even on non-contracted land, because their acreage of soybeans, cowpeas and all other harvested crops in 1934 could not be more than their harvested crop acreage for 1932 or 1933, whichever was the higher. However, even with the modifications, neither the fodder corn nor the sorghum can be planted prior to a date to be set by the Secretary of Agriculture. This date has not as yet been established in Illinois, but the decision is expected soon.

Green Wheat May Furnish Emergency Feed In Illinois

Cutting green wheat and other small grain crops for hay instead of harvesting them for grain is one way that Illinois farmers can meet the present serious feed situation, it is suggested by the College of Agriculture, University of Illinois. With the continuation of extremely dry weather and the devastating inroads of the chinch bugs, many dairymen face the most serious forage shortage in decades, it is believed.

Wheat has a high feeding value, if cut for hay in the early dough stage when the plants are quite green, according to W. W. Yapp, chief of dairy cattle at the college. When cut at this time, it has more feeding value than oat hay cut under similar conditions and is comparable to mixed clover and timothy hay. Where the chinch bugs have been prevalent in the wheat field, it is easily possible that the largest amount of digestible nutrients and the greatest feeding value would be gained by mowing it for hay.

"It should be borne in mind," explains Yapp, "that wheat hay should be fed in combination with a roughage of higher protein content, such as alfalfa, or should be supplemented with a grain feed containing relatively large amounts of protein. Adding ground soybeans or cottonseed meal to the grain ration will overcome the deficiency in the wheat hay.

The question of whether dairymen should cut their small grain for hay or harvest it for grain can not be decided for all alike, it is pointed out. Much depends on the probable yield of the grain, the price of wheat in relation to the price of hay, the prevalence of chinch bugs in the grain and the individual farmer's need for hay or roughage. These factors must be weighed on each farm before the final decision can be made.

Sunflowers May Be Utilized For Silage By Dairymen

Sunflowers may be grown by many Illinois farmers this year to make silage for their dairy cattle, as a result of damage to other crops by chinch bugs and drought, according to Prof. C. C. Rhode, chief in dairy extension at the College of Agriculture, University of Illinois.

The fact that sunflowers are chinch-bug resistant makes them a possible silage crop this year. In past seasons when the bugs have been bad, Illinois dairymen have grown sunflowers and have found that the resulting silage was fairly palatable, Rhode said. Cows fed sunflower silage, however, do not generally produce as well as those given regular corn silage.

Where barley fields have been practically destroyed by the chinch bugs, Rhode suggested that farmers may seed a portion of this land to sunflowers. The crop may be seeded any time prior to the middle of June, and is usually drilled in rows 42 inches apart with the plants 10 inches apart in the rows.

Experiments conducted at the College of Agriculture, University of Illinois indicate that the best time to cut sunflowers for silage is when about one-fourth of the plants are in bloom. Silage made from sunflowers at this stage is more palatable and is superior for milk production to that made from more mature plants. The composition and flavor of the milk are not affected by sunflower silage, Rhode said.

## Special Insect Distribution Aids Chinch-Bug Fight

Illinois gained something of a state credit in the distribution of government-made chinch-bug barriers during the week of June 10 to 12. The people of Illinois, preparing to sow a last stand to protect their corn crop, from which they have realized an average annual value of more than \$1,000,000 even during the last five years and on which they can ill afford to take losses this year.

By June 11, thousands of gallons of the insecticide were poured into the chinch-bug barrier of Illinois, it was announced by Prof. W. F. Flint, chairman of the state chinch-bug control committee and entomologist of the College of Agriculture, University of Illinois at Urbana. It is the first distribution of the insecticide in Illinois.

The insecticide was distributed in the form of small packets until 10:30 a. m. on June 11, and then in the form of large packets until 11:30 a. m. on June 12. The barriers are distributed in the form of small packets, one for each acre, and in the form of large packets, one for each 10-acre tract. The barriers are distributed in the form of small packets, one for each acre, and in the form of large packets, one for each 10-acre tract. The barriers are distributed in the form of small packets, one for each acre, and in the form of large packets, one for each 10-acre tract.

Prof. C. B. Miller, state leader in the extension service of the College of Agriculture, University of Illinois, and W. J. M. Isaacs, Director of the Illinois State Department of Agriculture, were other leaders of the committee.

Arrangements also were made for dealing with federal officials for the distribution of the insecticide, a gallon of which is now available in a number of counties through an Illinois corn supply company. Having this local supply gained an important time-saving for an operation, and such as most of the shipments of insecticide government orders theretofore had to be made from the officials of Chicago.

Barriers will be purchased in government orders in addition to a vast amount of private chinch-bug barriers, themselves, had bought before the federal chinch-bug bill was passed. Furthermore, for Illinois barriers, they have since last summer and fall been supplied by the College of Agriculture, University of Illinois and the Illinois State Bureau of Entomology and Plant Quarantine. Chinch-bug plague was rampant this season. They were forewarned of the danger in the state to get their materials ordered, their barriers built and their spraying operations commenced to minimize damage.

The week ending June 12 saw barriers preparing to see what was the last stand against the danger of the bugs. After that time it was believed that the pests could be so scattered in most counties of the state that it would be useless to try to protect corn. There may be some cases where barriers built after this week will still not be enough to save the crop, but such cases are few.

The slackening of the chinch-bug threat was indicated in reports which came from farm advisers as the deadline for barrier building drew near. Christian county reported an infestation so thick that Farm Adviser T. H. Brock claimed the chinch-bug "center of the world" for that county. Prof. Flint agreed. Formerly Christian was believed to have been the chinch-bug capital, but developments this season have shifted the "honor," or more properly the horror, to Christian, it was said.

### Early Feeding Of Grain To Pullets Insures Egg Cash

Pushing pullets for extra early fall egg production may be a tempting way of trying to improve the farm's cash income this year, but such pullets may "fade" out as layers and as a steady source of income, says H. H. Alp, poultry extension specialist of the College of Agriculture, University of Illinois. Eggs have brought Illinois farmers an average annual income of \$ , 00 , 00 during the past four years, and this source of cash probably will be relied on more than ever this year, he said.

Egg prices are generally at their highest in the fall months, and to take advantage of this market, poultrymen force their pullets into early production by continuing them on a mash higher in protein than is needed for good growth.

The all-mash system of feeding has proved quite satisfactory in many instances, points out Alp. However, when used incorrectly it is believed to be partially responsible for pullets "fading" out of production in the fall and winter, because of failure to secure good physical development during the growing period. Early maturity in pullets is desirable, but maturity at the expense of physical development is likely to prove unprofitable.

To help overcome erratic winter laying, it is suggested that growing pullets be fed for good physical development, such as may be obtained on many farms through the liberal feeding of grain. It is true that grain-fed birds may not come into production as quickly, but in the opinion of a number of practical poultrymen, they are likely to be more consistent in their winter laying.

A mixture of equal parts of cracked corn and sweet feed in a hopper, in conjunction with the regular mash, has given satisfactory economical results, Alp explains. As the birds become older, whole grain may be substituted for the cracked corn in the mixture.

### Liming's Effect Verified Today In Illinois Fields

Ben Franklin's old adage about "the best investment is a deposit in fertility" in a soil is being confirmed in 1934 by hundreds of Illinois farmers, says L. B. Miller, associate in soil experiment fields at the College of Agriculture, University of Illinois.

Farmers who in past years applied limestone to their soils so that they might grow a rich red and sweet clover, have found the investment to pay good dividends, and particularly so this spring. Drought in many Illinois counties dried up the bluegrass pastures, making them almost worthless by the middle of May, but legumes made possible by limestone applications have come to the rescue with both pasture and forage.

A typical example of such investment and timely dividends is found on the farm of Frank Hanley, in McLean county, Illinois, explains Miller. Back in 1919, Hanley applied limestone at the rate of 3 1/2 tons to the more on a 15-acre field. It was then conceded to be the richest soil on the farm and had not grown clover for years.

In the past 13 years, however, the field has produced several good crops of alfalfa and this spring exhibited an excellent growth of a red and sweet clover mixture. The field is being raised and the owner has remarked that it "couldn't have been a life saver this season with the bluegrass, it is of little or no value."

It is possible that the original 3 1/2-ton limestone application made 13 years ago will continue to give good results for many more years, points out Miller. If, however, it is assumed that it is now exhausted or leached from the soil, the cost at present prices has been only 45 cents an acre each year.

### Chopping Hay May Have Saved Harvest This Year, Feeds

Illinois farmers will not harvest their usual crop of 2,100,000 tons of hay this year, but that may be only one more reason why it will pay many of them to use the newer practice of storing it in chopped form rather than as long hay, in the opinion of R. H. Reed, agricultural engineer at the College of Agriculture, University of Illinois.

Farmers who have been using chopped hay say that less is wasted by the year, an important point when the crop is so small as it is expected to be this year, he said. As much as 25 to 30 percent may be wasted when coarse soybean hay or hay of poor quality is fed long, it is said.

Other advantages in favor of storing hay in chopped rather than unchopped form are savings in time, labor and expense, Reed reported.

From a questionnaire sent to farmers in many parts of the United States, it was learned that those who are now chopping their hay with a hay chopper or mangle cutter as it is put into the barn have found the practice so satisfactory that few, if any, would return to the use of long hay.

Among the many advantages noted in the use of chopped hay, explains Reed, is the elimination of work in the hot, dusty mow during cutting. Where a chopper is used at the barn, it not only cuts the hay into short lengths but also elevates it and places the hay in any part of the mow desired. This benefit was listed by every farmer answering the questionnaire.

In addition, farmers noted that the hay could be put up in a mow with fewer man-hours a ton, when it was chopped than when stored as long hay.

Many farmers also found that the saving of mow space which in the chopping of hay permitted advantageous changes in their farm buildings. Since the barn supports were strong enough, or could be reinforced, mow space that previously was hay could be stored in the new space or the extra space could be used for grain bins or other purposes.

Most of the farmers using chopped hay reported that less time and energy were required to throw the chopped hay down from the mow and feed it than had been required previously for long hay.

### Barnyard Kings Get Ax For Sake Of High-Quality Eggs

The open season for roosters is on in Illinois, and right now the life of the "King of the Barnyard," who plays the leading role in lowering the quality of summer eggs, is in a hazardous position, announces the poultry division of the College of Agriculture, University of Illinois.

Rooster days are being sponsored by farm advisers, chambers of commerce, newspapers and poultry companies in all parts of the state, with the result that wild birds, young and old, are being corralled for market. Premium prizes and prizes are offered to farmers who bring their roosters to town on special days.

Back of these rooster day celebrations is an almost statewide effort to produce higher quality eggs this summer and fall, it is explained. During the warm months fertile eggs are the first to deteriorate, but by removing the male bird from the flock, farmers can take the first step toward insuring better keeping qualities in their market eggs. Approximately \$3,000,000 is believed to have been lost by Illinois egg producers in one year as a result of marketing low quality and bad eggs, and to fertile eggs can be laid the blame for a large portion of this loss.

## Illinois Farmers May Next Make Against Chinch Bugs

Illinois farmers have waged such an intensive fight against the chinch bugs threatening their corn crop that by June 17 there had been distributed in this state a total of 1,257,700 gallons of the creosote and coal tar which the government purchased and furnished free to farmers for barrier building, it was announced by Prof. W. F. Flint, chief entomologist of the College of Agriculture, University of Illinois and Illinois State Natural History Survey.

Any further check on the pests by the use of barriers is now practically impossible in all of the 70 infested counties. For now on the chief activities in the fight will center in the late planting of emergency crops to replace those destroyed by the pests and the drought and in the possibilities of reducing damage from the second brood.

The amount of government-purchased oil used for barriers in Illinois reached the total of 1,257,700 gallons when the state was granted an additional 27,000 gallons on June 17. The state's original allotment was 200,000 gallons, but this had been increased by 200,000 gallons before the final additional grant of 857,700 gallons was made.

By June 17 the 11 states had used the entire quantity of barrier creosote and coal tar purchased by the government out of the special appropriation of \$1,200,000 which was passed on June 7.

Distribution of the 1,257,700 gallons of oil was made in Illinois without the cost of a cent for salaries, wages or other overhead, with the exception of transportation costs. Members of the state chinch bug control committee in charge of the distribution were Prof. Flint, chairman; J. C. Spitzer, state leader of farm advisers in the extension service of the College of Agriculture, University of Illinois, and Walter F. McLaughlin, director of the Illinois State Department of Agriculture.

Heavy rains in some parts of the state on June 17 caused no appreciable casualties in the hordes of chinch bugs. The pests continued to be just as serious a threat as ever to the corn crop, which farmers are now depending upon more heavily than ever as a result of the failure of many of their other crops.

Reports indicating that the rains did not lessen the dangers of chinch bug damage were received by Prof. Flint from a number of counties in the state. F. H. Thuman, farm adviser of Stateside county, reported that bugs submerged for two hours after heavy rains of June 17 appeared to be as lively as ever after the water dried off.

With everything done that can be done to check the bugs by means of barriers, farmers now are thinking and planning of what to do next. Suggestions to help farmers repair the damage that already has been done to their crops and to avoid as much damage as possible during the remainder of the season are being worked out by the chinch bug committee of the U. I. College of Agriculture composed by Prof. Flint, chairman; George G. Dungan, of the agronomy department; J. W. Lloyd, olericulture; W. W. Yapp, dairy husbandry; J. L. Edmonds, horse husbandry, and James R. Holbert, of the U. S. Bureau of Plant Industry, Bloomington, who is cooperating with the college.

Late Corn May Be Best Forage Crop On Illinois Farms

Despite probable damage by both chinch bug and drought, corn may yet prove to be the Illinois farmers' best bet as a forage crop this fall, in the opinion of G. H. Dungan, crop production specialist at the College of Agriculture, University of Illinois.

Corn is usually considered for its value as a grain crop, but in a forage shortage emergency such as may take place this year as a result of dry weather and chinch bug infestation, the plant may be called upon to exhibit its dual possibilities, it is said.

About the time the chinch bugs lay their eggs on the earlier planted corn, which usually occurs in Illinois about the last week in July, farmers may still plant corn that will develop a large amount of forage before the first killing frost, explains Dungan. Obviously such corn will not produce grain and it may not mature enough for silage, but it will prevent a forage shortage on many farms.

This corn should be drilled thickly at the rate of 1 bushels of seed to the acre, in much the same manner as soybeans. Heavy seeding is advisable to prevent the plants from becoming too coarse for the best livestock feed. There is no particular choice as to the variety, for any well adapted seed will produce sufficient growth for forage purposes.

Sometime before the first killing frost, when the plants are tall enough the corn may be pastured or cut for hay as the farmer desires. The green corn plants, however, should not be pastured after the first killing frost because of the danger of ruminant acid poisoning.

As a general recommendation, explains Dungan, soybeans, cowpeas, sudan grass, grain sorghum and millet are superior to corn for forage production. But this year reports indicate that most farmers have plenty of seed corn on hand, while the seed of other possible crops is becoming both scarce and expensive. Thus, in the absence of other seed and in light of threatening chinch bug damage, corn may prove the most practical emergency forage crop this fall.

-M-

Late Garden Crops Still Possibilities In Illinois

With the drought being broken throughout most of the state, Illinois home gardeners still have time to produce considerable food for their families, if they plant the proper crops, says Lee A. Somers, horticultural extension specialist at the College of Agriculture, University of Illinois. Probably some vegetables may yet be planted in most Illinois counties with reasonable assurance of success.

Partners can still get good, though late, crops of tomatoes, peppers, egg plant and sweet potatoes, if strong plants are used and growth is hastened as much as possible. Likewise, it is just the time of year to put out lima beans in northern and central Illinois, although a bit late for the southern part of the state. Furthermore, cucumbers, summer and winter squash and even an early variety of muskmelon such as Hale's Best may be planted, if no time is lost.

Sweet corn should be planted now and successively until as late as July 15. While string beans may be put out at regular intervals until late July. For those who like okra, a crop may still be had, if seeded promptly.

By dropping four or five seeds in each hill and later thinning out the plants until the most vigorous remain, Illinois growers may produce late cabbage and cauliflower crops. In the case of cabbage, however, only yellow-resistant varieties such as Wisconsin All-Head Select or Wisconsin Hollander No. 1 can still be planted.

To supply summer greens, the season is not too late for Swiss chard, chile and other crops that may yet be planted include sweet corn, Detroit Red cress, Red Top Turnip or Carmen No. 1 potatoes, pea corn and dry beans.

-M-

Phosphorus Test Aiding Farmers In Flexing AAA Acres

Perfected before AAA programs were started, the 1935 phosphorus soil test developed at the College of Agriculture, University of Illinois has come to the rescue of Illinois farmers who are participating in the government's adjustment program. According to reports by C. M. Linsley, soils extension specialist, more than 400,000 farmers in this state have signed contract to and some 25,000 are cooperating in the wheat control campaign.

To take part in the adjustment program, the farmers agreed to withhold from normal production at least 15 per cent of their former wheat acreage and 10 per cent of their usual corn ground. AAA regulations, however, permit the cooperators to use these contracted acres for certain purposes, one of which is the seeding of legumes for soil improvement and erosion prevention.

Desiring to grow certain legumes on the contracted acres, AAA contract signers must first know whether or not the contracted acres contain sufficient phosphorus to assure satisfactory growth. It was in such cases that the available phosphorus test proved its value in the government's adjustment program. The soil acidity test recommended by the U. of I. College of Agriculture, likewise, was of value in determining whether the proposed contracted acres contained enough lime to grow alfalfa, red and sweet clovers.

How the phosphorus and acidity tests actually aided farmers in avoiding serious mistakes is revealed in the personal experience of R. A. Congram of Ford county as reported by Farm Adviser W. F. Furnell. Congram had decided to seed his AAA acres to alfalfa and had located this plot where it would be most convenient for his tenant. However, before seeding time Congram attended a soil testing meeting conducted by Furnell in cooperation with the extension service of the college of agriculture. He took with him soil samples from the proposed contracted acres as well as from another field not so conveniently located but still available for the purpose.

When the tests were made at the meeting, Congram was surprised to learn that the first field was medium acid and low in available phosphorus, and therefore unsuitable for alfalfa without treatment. Field No. 2 proved to be sweet, with a fair supply of available phosphorus, and hence in good condition for alfalfa production.

Like many other farmers in various sections of Illinois who had similar experiences, Congram made arrangements to change the location of the contracted acres to the second field, thereby probably saving his alfalfa seeding.

-M-

Peach Thinning To Be Profitable Where There Is Crop

With prospects for good peach prices this year, southern Illinois growers can well afford to thin out the set to obtain the greatest possible yield of fruit of marketable size, says M. J. Dorsey, chief, and R. L. McMunn, of the division of pomology, College of Agriculture, University of Illinois.

Since the crop to the north of Illinois was frozen out this year, growers of this state seem to be in a strong position in the market. This alone will repay orchardists for bringing on a high quality crop, it was pointed out.

The buds that survived the low temperatures of the past winter are, for the most part, located at the base of the shoots, it is explained. This has resulted in so uneven distribution of the buds over the tree that a different type of thinning should be practiced. The usual attempt to space the fruit should be omitted this year in favor of thinning according to the total load of the tree.

## Increased Industrial Activity Bolsters Farm Prices

Brighter days for Illinois farmers have been ushered in with the continued well in factory payrolls, combined with increased industrial production, it is shown in a monthly review prepared by Dr. R. W. Bartlett, Agricultural Economist, U. of I. College of Agriculture. With grains registering the most marked advances, the index of Illinois farm prices prevailing in May was 10 per cent higher than a year ago, the review points out.

Business conditions in May remained about the same as they were in April, and up to that time the course of business activity in the United States had been definitely upward since November, 1933, Dr. Bartlett said.

About 1.1 billion dollars more was received by Illinois factory workers in April, the most recent month for which figures are available, than they received in April, 1933. Nevertheless, the April payroll this year was only 47 per cent of the April average for the years 1925 to 1927.

The total April income for factory workers in the country as a whole was 789 million dollars, which was an increase of 372 million dollars, or 75 per cent, over what it was in April, 1933, the review reports. However, the April U. S. factory payrolls in April of this year were only 67.3 per cent of what they averaged during April of 1925 to 1927.

The demand for food and hence the prices for farm products are influenced by such changes in payrolls of industrial workers, Dr. Bartlett explained.

"Prices of all Illinois farm grains in May of this year jumped 8 per cent above what they were a year ago. Oats, barley, wheat and corn made marked advances, while hay prices in May were 38 per cent higher than those of a year earlier.

"The principal advances in hay and grain prices can be attributed to actual or probable reduction in supplies resulting from the drouth, chinch bugs and farm adjustment programs, going along with a continued improvement in demand.

"Illinois livestock prices in May registered an 8 per cent increase over the mark of a year ago. Prices of lambs, sheep, horses, beef cattle and veal calves were higher than they were a year ago. The only classes of livestock to register a decline were hogs and milk cows. The average price of hogs was \$3.15 a hundredweight on May 15 compared with \$3.56 on April 15 and with \$4.30 on May 15 last year. The decline for the past month was partly seasonal and partly the result of a larger than usual increase in slaughter.

"Average farm prices of Illinois livestock products in May were 16.5 per cent higher than a year earlier, with wool prices showing the most marked gains. Farm prices for eggs were 13.5 per cent higher; for chickens, 9.4 per cent higher; for milk, 12 per cent higher, and for butterfat 7 per cent higher than last year. Wool prices were 45 per cent higher than those of a year ago.

"Indexes of Illinois farm prices of farm products by months in 1934 compared with the same month of 1921-1933 were: January 56, February 56, March 56, April 56 and May 75. The Illinois farm price index for May, 1934, was 10 per cent higher than a year earlier."

Lespedeza Straw Proves To Be Fair Dairy Roughage

Illinois dairymen faced with a shortage of forage for their cows as a result of the extreme drouth this spring will find threshed lespedeza straw a fair emergency roughage, suggests W. B. Havens, associate chief in dairy cattle feeding at the College of Agriculture, University of Illinois.

Experiments just completed by the dairy husbandry department show that although lespedeza straw can not be expected to be as high in feeding value as well-cured lespedeza hay, it is nearly equal to early-cut, leddy, green soybean hay.

When 12 dairy cows were fed lespedeza straw, Havens reports, they produced an average of 33.5 pounds of milk daily as compared to 25.5 pounds when fed soybean hay. The lespedeza straw in this case contained 7 per cent protein, while the soybean hay gave an analysis of 13 per cent protein.

Lespedeza is usually harvested for seed when the plants are well matured. At that stage the plants are lower in protein and are more woody than at an earlier stage when the best quality hay can be made. This probably accounts for the fact that the lespedeza straw was less palatable to the cows than the soybean hay. In spite of this difference, the cows consumed all but 16 per cent of the lespedeza straw, while they left 23 per cent of the soybean hay in the mangers in the form of coarse stems.

The lespedeza straw fed during these trials consisted of approximately 67 per cent leaves, 25 per cent stems and 8 per cent timothy stubble. This high percentage of leaves and the good results obtained are accounted for by the fact that the lespedeza was cut before complete maturity. All of the leaves were carefully saved, the straw was free from mold and in good feeding condition. The leaves of the soybean hay, which was harvested very early, formed about 64 per cent of roughage, the stems 31 per cent and the pods 5 per cent.

Thus, when handled in a manner that will conserve its feeding value, lespedeza straw may be depended upon to give fairly good results as a roughage for dairy cows, says Havens.

U. S. Inspections Speed Fruit And Vegetable Sales

Shipping point inspection service, now available in many parts of Illinois, is adding both speed and satisfaction to the sale of the state's \$25,000,000 fruit and vegetable crops, says J. W. Lloyd, chief in fruit and vegetable marketing at the College of Agriculture, University of Illinois.

Illinois growers are finding that official certification of the grade and condition of their products is especially helpful in making sales on telegraph orders, since the information supplied by the inspection service is recognized as authentic in both the trade and the courts.

On a falling price market, explains Lloyd, a car of either fruits or vegetables with an inspection certificate is much less subject to rejection than a car without benefit of such service. This is a valuable advantage to the shipper. Likewise, on a rising market, the distant buyer is more certain of getting what he wants, if he buys only on the basis of official inspection. Thus more satisfactory dealing all around is made possible through the inspection.

This shipping point service is furnished by the Illinois State Department of Agriculture in cooperation with the U. S. Bureau of Agricultural Economics and may be obtained by grower, shipping agent or buyer in all localities where early apples, sub-bags, peaches, tomatoes, and late apples are produced in sufficient commercial quantities.

Small Grain This Year Is suited To Good Combining

While 1934 brought drouth, chinch bugs and unusually short wheat and oats, it also supplied optimum conditions to combine-harvest Illinois small grain crops, says A. L. Young, agricultural engineer at the College of Agriculture, University of Illinois.

In most parts of the state this season, it is possible to let standing grain ripen thoroughly. There is little danger of lodging, and there are few weeds to increase in size as the grain dries. The fact that the grain is short will prove more of an advantage than a handicap to Illinois combine operators.

As a result of these favorable conditions, however, there will be a tendency on the part of operators to thresh unusually fast, throwing a heavy load of grain and chaff on the cleaning sieves and screens. This should be avoided, explains Young, for it is likely to cause difficulty in separating even the dry foreign material from the grain. If the sieve openings are kept small enough to reject heavy foreign matter, rapid threshing will cause heavy tailing, resulting in a fairly large loss of grain in chaff and straw. Furthermore, this may cause cracked kerns when excessive amounts of threshed grain are returned to the cylinder.

Short and very brittle straw to be found in most Illinois grain fields this year will tend to increase the amount of chaff that works down through the straw rack. This will increase the amount of chaff that must be handled by the cleaning sieves. On some combines the size of the openings in the rack conveyor can be made smaller to care for this condition.

To reduce the amount of chaff, it is generally best to use fewer concave teeth and keep them up well. Lowering the concaves may let an excessive number of heads pass through unthreshed, particularly when the straw is short.

Windrows containing this year are likely to prove somewhat rich. In fields where there are both short grain and weeds, operators should bear in mind that windrows not supported by a fair amount of stubble dip out very easily if so wet by a rain. Moreover, when windrows that consist mostly of heads are packed up, the amount of grain left on the ground will be high. Then too, windrowing short oats where the concaves have not been cut into short lengths is seldom advisable.

-M-

Practising Orchards Being Stored As Thing Of Past

Another of the older farm practices that is fast becoming a thing of the past in the 176,370 acres of Illinois orchards is clean cultivation, according to Dr. W. A. Ruth, chief in horticultural pathology at the College of Agriculture, University of Illinois. Although it gave orchards a look of beauty and of well-being, clean cultivation is now known to do more harm than good, he said.

It is true that cultivation at certain times provides the best conditions for growth, points out Ruth, but it also gives the way for soil erosion which is always more serious than it appears. Furthermore, excessive orchard cultivation reduces the available water supply for the trees. By creating a fast mulch, which water penetrates only slowly, cultivation causes the rain to run off instead of soaking into the soil. Likewise, continuous cultivation destroys organic matter.

No definite rule for cultivation can be prescribed for all orchards, says Ruth. The age of the trees, the topography and physical condition of the soil must be considered for each individual orchard in light of the benefit or harm that may accrue as a result of certain cultivating practices.

## Late-Sown Crops Must Produce Emergency Stock Feeds

Emergency feed to help cover the ten million head of live stock on Illinois farms can be obtained by planting some crops as late as the middle of August, according to a new circular, "Late-Sown Emergency Feed Crops for Illinois," which has just been issued by the College of Agriculture, University of Illinois to help farmers cope with one of the most serious feed situations in history. Dr. L. H. Smith, of the department of agronomy, is the author of the new circular.

Soybeans, cowpeas, corn, sudan grass, rye, millet, sorghum, rape and buckwheat for emergency fodder purposes may be planted in Illinois as late as the middle of August, the circular points out. It is too late to expect normal yields from these late-sown crops, even in the best or favorable weather from now on, but they will enable farmers to make the best of a bad situation.

A further development in the corn and chinch bug shortages of live-stock feed is the lifting of AAA restrictions to permit Illinois farmers to plant fodder corn and grain sorghums on any or all of the 50,000 acres of land which are being rented to the government under wheat, cotton and tobacco contracts.

For the most part, farmers have little choice between the different emergency crops because seed of most of them is scarce, it is pointed out in the college's new circular. It is being suggested that farmers use such seed as is at hand. If corn is available, as it usually is, planting it promptly when it is reasonably safe from chinch bugs will usually give better results than delaying to search for some other crop.

Sudan grass has given reasonably good results at the U. of I. college of Agriculture when it has been planted for emergency purposes as late as the middle of August. It is a fast grower and can be used for hay, pasture or silage. At the experiment station farm it was ready for pasture as early as four to six weeks after planting. One objection, of course, is that chinch bugs like it. Large seed dealers may be able to furnish seed. If not, inquire in Kansas, Oklahoma and Texas where sudan grass is grown.

Millet is another of the crops that can be sown late in the season. It is not so highly regarded as sudan grass, but seed of it can sometimes be obtained after the sudan supply is gone. This is another of the crops that the chinch bugs like.

Sorghum will withstand very hot, dry weather, but it is subject to chinch bug attack. There are many kinds of sorghum, and the crop can be used for hay, forage, silage, seed or the preparation of sirup.

Rape, one of the chinch-bug-proof crops, is used for pasture, especially for sheep and hogs. It should not be fed to dairy cows because it gives an off-flavor to the milk.

Buckwheat, another chinch-bug-proof crop, may be sown until midsummer for a seed crop. It will thrive on poorer soil than will many other crops.

A mixture of sudan grass and cowpeas has given good results on the experiment station farm of the agricultural college.

Banner Illinois Year Predicted For Legumes And Lime

With approximately 1,500,000 acres of Illinois corn and wheat land retired from normal production as a result of the government's adjustment programs, 1934 may become the banner year since 1930 in the application of limestone and the seeding of alfalfa and other legumes in this state, says C. M. Linsley, soils extension specialist at the College of Agriculture, University of Illinois.

This is borne out by reports from county farm advisers in all parts of the state. In all these reports there is evidence of a new and livelier interest on the part of farmers in the college's long-time program for more legumes and better balanced cropping systems.

Two of the most noticeable effects of the AAA in Will county are the increased demand for alfalfa and sweet clover seed and the increased use of the soil testing service to protect these new legume seedings, according to L. W. Braham, farm adviser at Joliet. "Up to May 1," Braham explains, "the demand for alfalfa seed increased more than 250 per cent and sweet clover seed 30 per cent over the amount purchased during the first four months of 1934. As a protection for these increased purchases, samples of soil representing more than 500 acres were tested and mapped during the month of April alone."

Thirty-two carloads of limestone were ordered by Peoria county farmers during April and May of this year, reports J. W. Whisenand, farm adviser there, while in Carroll county 15 crushers have been operated at local quarries to supply the limestone demands of farmers. "It looks like one of the high years for liming and sowing alfalfa," is the comment of M. P. Roske, Carroll county farm adviser.

Seedings of alfalfa in Stephenson county will be unusually heavy this year, if the number of soil tests and inquiries relative to the seeding of alfalfa can be taken as an indication, writes Farm Adviser T. J. Banter. In one month 407 acres of Stephenson county soils were tested for acidity and hundreds of inquiries received relative to legume production.

The corn-hog program has directed the attention of Douglas county farmers to the importance of crop yields, and as a result there is a growing interest in legumes this year, Farm Adviser Ware C. Ogden reports. A similar trend is noted in Edwards county where Farm Adviser W. D. Murphy reports gains in alfalfa acreage. Sales of alfalfa seed in De Witt county have been several times higher than normal, in the opinion of Farm Adviser H. N. Myers, and E. J. Amrine, farm adviser in Wayne county, reports several hundred tons of limestone ordered for farmers in his county.

-M-

Use Of Tractors Making Abnormal Gains In Illinois

An abnormal increase in the use of tractors is taking place on Illinois farms today as a result of the steady decrease in available work horses and the improvement in tractor and tractor equipment, says R. I. Showl, assistant chief in agricultural engineering at the College of Agriculture, University of Illinois. The latest available census figures credit Illinois farmers with nearly 70,000 tractors, or an increase of almost 61 per cent over the 1925 tractor enumeration of 43,525.

This trend in the use of mechanical power has been stimulated in the last few years by a decided increase in the over-all efficiency of tractors, resulting from improvements in design, material and construction. Quality, dependability, adaptability and long life are now demanded by and available to tractor buyers.

Furthermore, in their efforts to reduce crop production costs, Illinois farmers who grow row crops have been attracted to the modern general-purpose type of tractor with its multiple-row cultivating and planting equipment, explains Showl.

-M-

The first part of the document discusses the importance of maintaining accurate records of all transactions. It emphasizes that every entry should be supported by a valid receipt or invoice. This ensures transparency and allows for easy verification of the data.

In the second section, the author details the various methods used to collect and analyze the data. This includes both manual and automated processes. The goal is to ensure that the data is as accurate and reliable as possible.

The third section describes the results of the analysis. It shows that there are significant trends in the data, particularly in the areas of sales and expenses. These findings are crucial for understanding the overall performance of the organization.

Finally, the document concludes with a series of recommendations for future actions. These include improving data collection methods, enhancing the accuracy of the records, and implementing more robust internal controls.

CONCLUSION

In conclusion, the data analysis has provided valuable insights into the organization's financial performance. The findings highlight the need for more rigorous data management practices and more frequent reporting. By addressing these issues, the organization can improve its financial health and ensure long-term success.

The author believes that these recommendations are essential for the organization's future growth and stability. It is hoped that these findings will be taken into serious consideration by the management team.

Delayed Peach Spray Likely To Pay Well This Year

With prospects for higher prices this summer, Illinois peach growers who are fortunate enough to have a crop will save money and get better results if they delay applying the usual sulphur sprays or dusts until two or three weeks before harvest.

This is especially true this season because of the dry spring and the light infestation of curculio, advises H. W. Anderson, chief in pomological pathology at the College of Agriculture, University of Illinois.

Brown rot, the most serious fungous disease of peaches does not cause much damage until the peaches approach maturity, it is explained. In seasons of heavy, early-summer rainfall, some fruit rotting may occur four or five weeks before maturity, but this is rare under Illinois conditions.

Since sulphur sprays or dusts are good insurance against brown-rot damage, growers will make a serious mistake, if they neglect this practice and allow the disease to become established in their orchards. With a general scarcity of peaches and higher prices for quality fruit, the protective spray will pay good dividends on time and money expended.

The most effective spray schedule for brown rot is one application about two weeks before harvest and another as near harvest as possible. Wettable sulphurs which do not stain the fruit or lime-sulphur dusts should be used. Lead arsenate should not be added to the spray at this time, and lime may be omitted when the wettable sulphurs are applied.

Although some buyers are inclined to discriminate against fruit showing evidence of spray materials, neither the lime nor the sulphur is injurious. Furthermore, the presence of brown rot is likely to cause greater market loss than the appearance of a small amount of lime or sulphur on the peaches, it is said.

-M-

Big Investments In Livestock Justifies Having Shade

An investment of more than \$140,000,000 which Illinois farmers already have in livestock readily justifies the small amount of money and labor that might be spent in supplying shade for their animals during the extremely hot days of mid-summer, says W. A. Foster, farm building specialist at the College of Agriculture, University of Illinois.

Sunlight in the winter is a tonic, giving warmth and comfort to all animal life, points out Foster. But in summer it becomes so intense and severe that livestock should have protection from its blistering rays in the middle of the day. Today many Illinois pastures are void of shade and the animals confined in them must suffer from both extreme heat and insect pests.

If trees are not available for shade, artificial protection can be erected with small cost and a little labor, Foster explains. A few posts and poles covered with brush or wire, then a thin layer of stalks, weeds or straw will give adequate shade. The rain will pass through this thin structure, thereby reducing the dust caused by the stock stamping at flies.

In line with the renewed interest in soil conservation and reforestation, setting out a few trees in each field and pasture will supply a shade in a few years that will pay large returns on a small investment. In carrying out such a plan, farmers should use care in selecting the trees, choosing healthy, quick-growing varieties that will become beautiful, hardy specimens. A protecting barrier should be built around the trunks of these trees so they will not be injured by the animals. This will not only provide shade for the livestock, but will add beauty to the farmstead.

## First Illinois Corn-Hog Contracts Now In Washington

Approximately 17,000 Illinois farmers who have signed corn-hog contracts are looking forward to the arrival of the first checks for close to \$35,000,000 in benefit payments, following the announcement by officials of the College of Agriculture, University of Illinois that the first of the contracts from this state have been sent to Washington.

The first contracts--87 in number--were from Piatt county and were mailed to Washington Saturday night, July 7. As soon as the contracts are checked and accepted by the Secretary of Agriculture, the first checks for benefit payments to farmers in this state will be started back from Washington. All those in the first assignment were early payment contracts, that is, the farmers signing them agreed to accept changes in their contract figures without having the changes submitted for approval.

Sixteen other counties made progress toward getting their checks when it was announced that they had adjusted the contracts of their farmers to meet the quotas of corn and hog production as set by the state board of review. Four other counties on Monday, July 9, had all but completed the adjustment of their contracts for final approval and five other counties will probably get the work finished this week, it was announced by A. J. Surratt, state agricultural statistician and chairman of the state board of review.

The 16 counties that have just met their quotas are Boone, DuPage, Lake, DeWitt, Piatt, Effingham, Fayette, Monroe, Williamson, Saline, Wabash, Washington, Clark, May, Cumberland, and Moultrie. Six counties that had completed the work earlier are Cook, DeWitt, Bond, Calhoun, Lawrence and Gallatin.

The four counties next in line to meet their quotas are Scott, Ford, Massac and Edwards. The five which probably will get the work done this week are Cass, Christian, Greene, Madison and Crawford.

After the counties have met their quotas, all that remains to be done is to get the contracts typed in final form, signed for the second time by the producers and then sent to Washington, after the necessary clearance papers have been obtained from the state board of review.

With the payment of benefit checks to corn-hog farmers just getting started, more than seven million dollars had been distributed up to the first of July, according to word received by the U. of I. College of Agriculture from AAA headquarters at Washington. Nearly 65,000 farmers had shared in these first payments, most of which went to those who signed early payment contracts.

Once they are sent in to Washington by the county corn-hog production control associations, the contracts are handled at the rate of 40,000 a day. A rate could be even speedier than this and the checks could be sent back still sooner if the contracts were absolutely free of mistakes. When examiners find mistakes and inadequate information in the contracts, the AAA must write a letter to the county corn-hog production control association to get the correct facts. This takes time, but care of his kind must be exercised in dealing with more than a million cooperating corn-hog farmers throughout the United States, it was pointed out.

Details Of AAA Wheat Program Remain Much The Same

Approximately 75,000 Illinois farmers who are cooperating in the government's AAA wheat program were assured three million dollars, or about that much, in crop insurance and benefit payments on their 1934 crop when Dean Herbert W. Mumford, of the College of Agriculture, University of Illinois, received official word from Washington relative to plans for the coming year's wheat program.

The required reduction in wheat seedings for harvest in 1935 is to be 16 per cent from the base period of 1925-1929, the same as was the case last year. However, the announcement stated that more details were being sent in amplification of this point.

Benefit payments for making this adjustment are to be paid to the cooperating farmers at the rate of .3 cents a bushel on 74 per cent of their average production during the base period of 1925-1929, the same as was the case last year. The purpose is to give cooperators a parity price on that portion of their wheat which goes into domestic consumption, and that portion is about 74 per cent.

Twenty of the .3 cents is to be paid this October and the remaining nine cents less local administrative costs, next June.

The total benefit payments for the state figure up close to three million dollars less the cost of local administration.

The processing tax of .20 cents a bushel is to be continued as a means of financing the wheat program, according to the word received by Dean Mumford.

Announcement of the AAA wheat plans for the coming year continues a wheat adjustment program which Illinois farmers have been carrying on for about a score of years. Between 1914 and 1933 farmers of the state, guided by the teachings of the extension service, U. of I. College of Agriculture and their county farm advisers, cut their annual acreage of winter wheat 50 per cent, or more than one-half.

-11-

Spreading Chinch Bug Fungus Fails To Check Insects

While some method of stamping out the chinch bugs now threatening Illinois corn fields would be welcomed, there is no hope that it can be done by spreading spores of the chinch bug white fungus disease or by putting out bugs that are infected with the disease, according to W. F. Flint, chief entomologist of the College of Agriculture, University of Illinois and Illinois State Natural History Survey.

If the weather should continue normally dry, the disease will not spread to other chinch bugs, and even the distribution of large quantities of the disease spores will have no effect on reducing the number of insects. If the Illinois corn belt should have an unusually wet summer, the disease will spread naturally without artificial propagation or spreading.

Fifty years ago, during the heavy chinch bug outbreak in 1867 to 1877 and for a number of years thereafter, experiments were carried on in Illinois by the late Dr. Stephen A. Forbes and Dr. Snow of Kansas in an attempt to kill the chinch bugs by spreading the disease among them. For a time it appeared that this method of control would prove successful. Continued studies, however, gave disappointing evidence.

The Natural History Survey from 1910 to 1915 developed a method of growing the disease on different types of media and was able to produce spores by the hundreds. As long as the weather remained dry, it was found that putting out spores even by the peck in infested fields had no effect in killing the bugs. If the weather became wet for a considerable period, the disease always appeared naturally and there was no advantage in spreading diseased chinch bugs or disease spores.

-12-

### Silos Aid Illinois Farmers In Acute Forage Shortage

Silos are coming into such importance as a result of the critical feed situation that one farmer even wanted to know how he could move a concrete silo instead of building another, according to W. A. Foster, farm building specialist of the department of agricultural engineering, U. of I. College of Agriculture.

Extremely dry weather and the chinch bugs have combined to reduce the amount of hay and other forage that are normally stored for winter livestock consumption. But on farms with silos, this loss can be overcome at least partially by putting up additional silage. Corn planted or re-planted too late to mature for grain will make good silage. Furthermore, such chinch-bug resistant crops as sunflowers, soybeans and cowpeas may be made into silage. Where grain sorghum is grown, this too may serve as a substitute for the more common corn silage.

Directions for successfully moving a concrete silo, which at least one farmer wished to do, would be hard to give, but if a new silo of any kind is to be built, there are certain things that must be kept in mind, Foster pointed out. In the first place, the structure should be strong enough so that it will not burst under great pressure. It should be smooth on the inside so that the ensilage will settle freely, and leak-proof so that the juices will not seep away and air enter to cause spoilage. The silo should be economical, of ample capacity, storm and fire-proof and attractive. The latter feature may not be essential, but it will add to its value as a permanent improvement in the farm building group.

Whether or not a silo is necessary on most Illinois farms is, of course, debatable in some cases, says Foster. However, with the increased difficulty of earning a livelihood out of the soil because of keen competition, insect pests, drought and floods, late freezes and early frosts, the silo is becoming increasingly important in Illinois farm operations.

Silo filling is hard work, but it is all done in a few days in late August and early September. Then the farmer has available, in a 100-ton silo, sufficient feed to carry a herd of 25 cows through the winter with enough silage left over for four to six weeks feed during the summer when pastures are short.

-11-

### Close Inspections Cut Repair Costs On Farm Tractors

Some kind of a long-distance record is likely to be claimed by a ten-year-old tractor at the College of Agriculture, University of Illinois, and many of the 70,000 tractors now being operated by Illinois farmers would do as well if they were given the proper care, says R. I. Shawl, of the department of agricultural engineering.

For the past nine and a half years, the U. of I. department of agricultural engineering has supervised the operation of a tractor during which time it has completed nearly 6,000 hours of general farm work. The average yearly cost of repairs for this machine has been \$59.37. The tractor is still good for several more years of work and need not be "junked" until the hourly cost of operation exceeds that of the newer and better tractors of present manufacture.

No matter how well a tractor is cared for, there will be some wear, breakage and need of repair, explains Shawl. These repair costs, however, can be reduced to a minimum by daily and yearly inspections and the use of high-grade oils, greases and fuels supplied from clean containers. Checking over a tractor each year locates all the loose bolts and nuts and the parts that need adjusting or replacing, thus preventing serious delays in the field. Taking care of every repair or adjustment as soon as it is found also adds to the life of a tractor and reduces maintenance costs.

Lazy Pigs Haven't Paid A Penny For Time In Field

"Lazy" pigs will be no more profitable this year than they have been for the last 10 years, in spite of the fact that the country's swine production is at the highest in years and the price of pork is a record in view of a record high.

This is the opinion of W. F. Carroll, chief of the swine industry, chief of the Department of Agriculture, University of Illinois, who says the "lazy" pig is now being carried on light feed and is not producing as much gain as it should of fattening than an average pig.

Now is the best time for a farmer to make a selection of a team of corn to give his pigs a good start in the fall, he says, by giving them the following feed, Carroll said. Start with a pound of alfalfa hay, but switch to a mixture of a 50-50 corn and alfalfa mixture when the pig is 10 to 15 years. This year would feed 70 pounds of alfalfa hay and 100 pounds of corn, but next year the difference in favor of alfalfa would be 100 pounds. These computations consider the difference in price of alfalfa hay and corn, and do not take into account that light-fed pigs would probably cost more to raise than heavy-fed pigs.

"Lazy" pigs that are allowed to loaf all day and do not move around rapidly require more feed than those that move around rapidly, and those that move around rapidly are likely to become runty. To avoid this, it is better to have a pig that is active and will move around rapidly than a pig that is lazy and will not move around rapidly.

That slow gainers are usually the result of a pig that is not active is shown by a study of 147 pigs fed individually at the University of Illinois. Of the 147 pigs, 70 head gained more rapidly than the average of all of the 77 slow gainers. In the 70 rapid-gaining pigs, 45 ate less feed in weight than the average of the 77 pigs of the group, while of the 77 slow-gaining pigs, 40 ate more feed than the average of the 77 pigs.

Spring-fed pigs that are not active and do not move around rapidly are not better than the usual fall pigs, and are not as profitable, but they do not gain more slowly than those that are active in the fall. With fall-barnyard pigs the relationship is usually lower than that, though it is often in contact.

-4-

Produce From Large Farm Produces A Good Profit

Produce from a large farm in Illinois, which has been producing about 100 tons of produce a year for the last 10 years, has been sold on the market before the produce is sold, it is reported by W. A. Hansen, assistant chief of research at the University of Illinois, University of Illinois.

Along the western coast, where growing conditions are usually better, some of the produce is often produced in the best form, though it is usually sold later and the earnings are generally not so good as those of the produce that begins to ripen. The situation in Illinois will most likely adjust itself to the needs of those growers who are contracting to produce for the first time learn that the price of the business is just as established as growing for market, and that they do not necessarily sell well, Hansen believes. The large grower, however, is not in the same position.

Production of canning tomatoes is on the increase in Illinois, because the prices are rising by millions after a short-term of several years, Hansen says. In addition many sections of northern Illinois are growing tomatoes for the first time this year on contract for a large eastern concern which is building a new factory in Chicago. In the peak year of 1925, some 7,000 acres were devoted to raising canning tomatoes in this state.

-4-

Eight Mistake Limit Proper Possibilities Of Pullet

Eight common errors are largely responsible for the wrong, weak, non-laying pullets found among Illinois' 6 million farm chickens along about October of each year, says H. H. All, poultry extension specialist at the College of Agriculture, University of Illinois.

During the summer months many farmers do not "go overboard" and consequently neglect the care of the birds when they lay and set the nest. As a result of this neglect, the pullets are so stressed that they fail to produce the number of eggs that might ordinarily be expected of them. Pullet ailments usually administered as cure-alls seldom give satisfactory results in the long run, and the poultryman finds that efforts to remedy the mistakes are expensive, difficult and completely ineffectual.

Among the common mistakes listed by All are: Eight feeders, empty water troughs, dirty brooder houses without screens, lice and mites in the brooder houses, old contaminated range, outdoor feeders, filthy yards, no clean and sanitary and sick birds allowed to remain in the flock.

Probably the greatest error in poultry management, as far as feeding is concerned, is failure to use the kind of feeder most suited to the prevailing conditions and growing pullets. The outdoor feeder is the best for use in the brooder house and so constructed that it will not only prevent waste and contamination of the feed, but will also keep the chickens dry. For each brooder house there should be at least two good-sized feeders. Many poultrymen are accustomed to use the same for the wash.

Failure to move the feed hoppers is also a common error. Unless the feeder is placed on a wire platform, the ground around it will soon become infested with poultry manure, and the danger of chicken mites, lice and parasites will increase greatly.

Like the feed, the water should be free of dirt and contamination. Cleanliness around the drinking trough is extremely important. A good plan is to place the trough on a low, wire platform so that the birds cannot get into it and soiled by spilled water. Furthermore, the trough should be filled with water regularly so that there is always plenty of water for the birds at all times.

-4-

Special Interest In Fall Garden Plants Salad Heads

Illinois gardeners who are spring planting early & disseminating seeds as a result of the severe drought from mid-April to mid-June will find Chicago or curly cabbages a worthy addition to the fall garden for fresh salads, broast and cooking, suggests E. L. Weaver, horticultural specialist at the College of Agriculture, University of Illinois.

Of the heading sorts, the narrow-headed type has been found to mature more rapidly, a higher percentage of plants head out under favorable conditions, they are fairly uniform in size and shape and will pack well for shipment. Three of these varieties, the P-Toni, Special Narrow Head and Nebull, have been tested at the U. of I. College of Agriculture with good results.

For home use or local market, the dense headed type Chicago yields much finer quality for salads or is less susceptible to disease than the other types.

Seed of the main crop is usually sown in central Illinois about July 1, and August 1 plantings will mature if the fall is seasonably favorable and if winter does not arrive too early. All plantings should be well watered and should be irrigated, for poor results can be expected when water is not available.

## Crop Production: Impact of Improved Price Situation

With reductions in both carry-over and current production, Illinois farmers should enjoy a more favorable price situation this fall than they have in recent years, says R. C. Ross, assistant chief in farm management at the College of Agriculture, University of Illinois.

A summary of carry-over as of July 1 shows that Illinois farmers had less than half as much corn and soybeans as they did last year at this time and about two-thirds as much as in 1931. Wheat carry-over in this state is 12 per cent less than a year ago.

Excepting possible winter damage by the usual bugs, the 1934 corn crop may be about 81 per cent of normal this year. This will be 9 per cent larger than that of 1931 and a 16-per-cent smaller harvest. However, it is too early to fully estimate the probable chinch bug damage, points out Ross.

Illinois winter wheat production this year has been estimated at 39 per cent of normal or slightly less than last year, but the oats crop is likely to be only 65 per cent of the normal level and 31 per cent of the five-year average. Both druth and chickling peas are expected to be produced in the exceedingly low yields production, while barley for distilling, if it is not destroyed in a normal crop, but in a much reduced crop.

The soybean crop for the country is estimated at 57 per cent of normal with timely and heavy rains estimated about 75. The yield, which is held by the drought, stood up much better this year than last year. Soybeans have been increased 170 per cent over normal plantings and yields are expected to be 20 per cent. This represents increased expansion in the soybean crop of 1934, which is related to the government under the terms of the Agricultural Adjustment program. A much larger proportion than usual of the soybean crop is expected for use to supplement the scant supply of other legume crops, it is believed.

Crop production for the country as a whole is also much below normal. Based on estimated acreage and yields in previous years, increases for 1934 for corn will be 83 per cent of normal, all other crops 48 per cent and hay 14 per cent. The acreage of soybeans, however, is expected to increase 13 per cent above the five-year average.

-11-

## Weather Holds Key To Success Of Chinch Bug Plague

If the weather turns dry, chinch bugs may destroy between 30 and 40 per cent of the Illinois corn crop, according to estimates made by H. P. Flint, chief entomologist of the Illinois State Natural History Survey and of the College of Agriculture, University of Illinois. However, wet weather conditions next two or three weeks will hold the damage down to 10 or 15 per cent of the crop. Whether or not the insect will be abundant and destructive next year depends upon the weather between now and spring, Prof. Flint said.

-11-

Illinois Farmers Making Record Use of Electricity

In spite of the fact that agriculture is just emerging from two years of record low prices, Illinois farmers are using more electricity today than ever before, it is revealed by a rural electrification survey recently completed under the supervision of the College of Agriculture, University of Illinois.

Farmers who recently have secured electrical service for the first time far outnumber those who discontinued the service as a result of the depression, the survey showed. Furthermore, in general those who have discontinued the service made little use of it when they had it.

The survey covered 12 representative Illinois counties and was made as part of a CWA project.

On the basis of findings made in the survey, 43,570 of the 14,495 farms in the state have electricity, while the remaining 170,927 would like to have it, according to E. W. Lehmann, head of the agricultural engineering department of the college. Although there are many farmers who are not financially able to have electric service, all of those interviewed said they would like to have it. Thus, if they had some satisfactory means of financing the building of lines, purchasing the equipment and buying energy, they would invest in this type of improvement as well as in automobiles and tractors, Lehmann believes.

Of the 43,570 Illinois farms which have electricity, 29,330 are on power lines while 14,240 have home plants. Likewise, the survey disclosed that 2,960 of the total number have electrically operated water systems, and 3,690 have electric stoves. There are 4,870 mechanical refrigerators, but since there was no distinction made between the various types of mechanical refrigerators, the survey does not indicate the number that are electric or gas operated.

There is a greater interest in the use of electricity for refrigeration than for cooking on Illinois farms. This is no doubt caused by the fact that fuel for cooking can be obtained easily on most farms and a reasonably satisfactory means of cooking is already available.

-M-

Oats Sown With Alfalfa Lessen Damage From Erosion

Damage from dust storms which proved so devastating to young alfalfa seedlings in sections of Illinois this spring, can be practically eliminated if oats is sown as a nurse crop with the new alfalfa seedlings this fall, says C. H. Farnham, assistant in soil experiment fields at the College of Agriculture, University of Illinois.

Largely as a result of the poor stands of forage caused by the drouth this spring and the provisions of the AAA programs in which some 125,000 or more Illinois farmers are cooperating, it is anticipated that an exceptionally large acreage of alfalfa will be seeded throughout the state during the next six weeks. An appreciable amount of these seedlings will be on sandy or light wind-blown soils which are subject to wind erosion capable of ruining seedlings made during the latter part of the summer.

Tests at the Oquawka soil experiment field, maintained in Henderson county by the U. of I. College of Agriculture, show that this damage may be largely done away with by the use of oats as a combination nurse and cover crop for fall-seeded alfalfa on sandy land, points out Farnham. Observations made at the Oquawka field this spring disclosed no damage to alfalfa seeded last fall where surrounded by good oats growth. However, a few feet away where no oats had grown the alfalfa was either badly damaged or entirely killed by the wind-blown sand. In a larger unprotected area on the field, sand had drifted several inches deep, completely burying a strip of bluegrass.

Washer Plans Aid Apple Men Meet New Residue Limits

Illinois commercial apple growers may not need to buy new washing machines, in spite of the more strict regulations placed on the amount of lead and arsenic residue permitted on apples for interstate and international shipment, in the opinion of E. H. Reed, agricultural engineer at the College of Agriculture, University of Illinois.

Remodelling the apple washing machines now in use so that the chemical washing solutions may be heated to a temperature of 90 to 110 degrees Fahrenheit will materially increase the amount of residue removed, and in many cases will eliminate the necessity of buying a new washer, says Reed. This heating can be accomplished with electric, hot water or steam heating systems as described in a mimeographed publication written by Reed.

Washing apples has come to be regarded as an accepted part of the production and marketing program of many Illinois fruit growers. In past years a few growers washed their apples to improve the appearance of the fruit, but since tolerance limits have been placed on the amount of spray residue that may be present on fruit to be shipped in interstate and international commerce, the washing practice has become more common.

Brushes, sprays and other mechanical means, as well as a variety of chemicals and wetting agents have been used to increase the percentage of residue removed. However, in seasons and areas where particularly heavy spray applications have been required to combat fruit diseases and insects, many of the washing machines in use will not remove enough of the lead and arsenic residues to meet present regulations. This problem brought about the development of the heating process.

Tests at the U. of I. College of Agriculture show that six times as much residue remains on apples washed in solutions at 65 degrees temperature as remains on those washed in the same type of machine at 110 degrees. Detailed information on installing the heating systems may be obtained by writing the department of agricultural engineering, College of Agriculture, University of Illinois, Urbana.

Six Contests Scheduled To Settle Team Pulling Honor

Two out of Illinois' 727,000 acres will be acclaimed the champion pulling team of the state following six horse-pulling contests to be held during the months of August and September, it is announced by E. T. Robbins, livestock extension specialist at the College of Agriculture, University of Illinois.

The first of the contests will be staged during the state fair at Springfield on August 21 and 22. The next will be at St. Joseph in Champaign county on August 28, and the third at Roseville in Warren county on August 31. Augusta in Hancock county will be the site of the fourth contest on September 4, while the remaining two will be conducted at Sandwich in DeKalb county on September 5 and at Tuscola in Douglas on September 15. Teams from all of the surrounding and nearby counties are expected to be entered in the respective pulling contests.

A dynamometer owned by the U. of I. College of Agriculture and operated by members of the agricultural extension service staff will be used in determining the pulling power of the teams taking part in the contests. Competing teams will be divided into two classes, those with a combined weight of less than 3,000 pounds and teams weighing 3,000 pounds or more.

Last summer the 4,000-pound team owned by Willard Rhoads, of Springfield, set the state record in the class of heavy teams by exerting a pull of 3,325 pounds for 7½ feet. This was equivalent to pulling five 14-inch plows cutting furrows six inches deep in stubble ground.

## Trench Silo Means Of Conserving Shrinking Corn Crop

With Illinois' corn crop threatened by the prolonged drought, as well as the pest period. Hunch bug infestation in half a century, many farmers of the state may be able to save the maximum amount of their corn by constructing trench silos, suggests J. W. Lehmann, head of the agricultural engineering department at the College of Agriculture, University of Illinois.

Reports indicate that the corn stalks are beginning to dry up in some areas. If extreme heat and dry weather should continue, farmers will want to take immediate steps to conserve as much of their corn as possible in the form of silage. In such cases, mimeographed instructions on digging trench silos, published by the U. of I. College of Agriculture will be of considerable value.

A trench silo is merely a large ditch with the ends on an incline so that a team or tractor can be driven through it. Practically all construction may be done with a clip shovel and consequently the expense is extremely small. The slightly sloping sides are later smoothed off with a spade.

The size of the trench will, of course, depend upon the amount of livestock to be fed from it and the condition of the silage at the time of cutting. A good-size trench silo is about 3 feet deep, 8 feet wide across the bottom of the trench and 10 to 12 feet wide across the top. The length will depend on the amount of silage to be cut up. If allowance is made for spoilage, 30 to 35 cubic feet will be required to store a ton of silage for feeding.

Selection of a site with good drainage is important in constructing a trench silo. A soil which is too sandy or one in which the water table is too high is not satisfactory. An objection against trench silos is the accumulation of water when there is a heavy rainfall. This can be overcome to a large extent by laying a drain under the trench, or perhaps the trench can be located so that the lower end opens onto a slope.

Because trench silos are not very deep, the silage does not pack much by its own weight, and thus should be tramped by men, animals or a tractor during and after filling. It keeps best if covered with straw and then several inches of dirt to make a rounded top to shed water.

An experimental trench silo built in another state was filled with 115 tons of silage, and a shrinkage of about 14 per cent, or one-seventh, was noted. About half of this was spoilage. Most of the spoilage occurred at the top, indicating that it is necessary to cover the silage well. When the silo is opened, the silage should be removed from one end and the silage taken from the entire end section each day so as to reduce the danger of spoilage.

More detailed information relative to the construction of trench silos may be obtained by writing the agricultural engineering department at the College of Agriculture, University of Illinois, Urbana.

-M-

Hail Damage to Corn May Show Little or No Loss

Corn struck by a hail storm such as visited several Illinois counties recently may not always turn out to be a complete loss, says G. H. Dungan, associate chief in crop production at the College of Agriculture, University of Illinois.

Much depends upon the severity of the storm and the stage of the corn at the time of the storm. Hail seldom removes all the blades, but more often splits and shreds the leaves to a greater or less degree. This type of injury is not so serious as complete blade removal.

Experiments conducted by the U. of I. College of Agriculture, in which the blades of corn plants were split as if hit by hail, showed only one-fourth the reduction in grain yields as compared to corn plants in which all the blades were removed, points out Dungan. This indicates that as long as a piece of green leaf is hanging on a plant, it is functioning in the direction of grain formation. For this reason, crop insurance adjusters usually like to wait as long as possible after a hail storm before appraising the damage. This gives the corn plants an opportunity to recover to the maximum extent.

Furthermore, if the storm should strike before the plants are tasseled and if the growing points are not broken out, corn can recover to a surprising degree. The emerging tassel brings a crop with it two or three blades which because of their newness and excellent exposure to the sunlight are very efficient aids in grain formation. However, if the corn is fully tasseled at the time of the storm and the hail beats off the blades, there will be little or no growth of plant or ear thereafter, explains Dungan.

Plants like soybeans and tomatoes which can send out new growth from buds that have been dormant may often show a marked improvement two or three weeks after a hail storm. Agricultural handling experiments with corn, however, show that it has much less capacity to survive a hail storm.

-M-

Utility Instead Of Faddish Breeds Best Profit Makers

Ever-winning livestock fashions may come and go like feminine styles, but Illinois producers who strive to obtain the maximum returns from their best animals should select their breeding stock more along utility lines, says E. J. Robbins, livestock extension specialist at the College of Agriculture, University of Illinois. Only farmers who raise the type and size of animals demanded by consumers can expect to sell their livestock for the highest prices, regardless of the latest mode at the livestock shows, he says.

At present many cattle raisers are finding that the fashionable little bulls beget calves that grow too slowly, points out Robbins. When ready for market these yearlings will weigh only 800 pounds, while somewhat coarser stock will tip the scales at half a ton. It is the larger yearlings that are making the most money because they more nearly fit the needs and desires of the market. Larger sires will aid many cattle-men in producing the larger, more desirable yearlings.

Likewise, early lamb producers are coming to realize that they need rams of considerable size, if they are to get the largest possible market returns. For this reason, many farmers are changing to the larger breeds of sheep. In the case of hogs, however, boars weighing considerably less than 1,500 pounds are more likely to fit the needs of most producers, rather than the excessively huge sires seen at fairs and livestock exhibitions.

Some breeds of livestock need more stretch while others need more compactness to supply sires for most farm herds and flocks. Thus the breeder who adapts his stock along utility standards will render a practical service for the livestock industry, says Robbins.

New Steps Taken To Raise Quality of Illinois Wheat

A new drive to further improve the quality of Illinois' wheat crop valued at an average of more than \$1 million dollars annually is on, it is announced by J. C. Jackleman, crops extension specialist of the College of Agriculture, University of Illinois.

As part of the work, 10,000 bushels of seed wheat already have been signed up for a new cleaning service that has just been started in five soft winter wheat counties of southeastern Illinois. It is estimated that as much as 40,000 bushels of seed wheat in those five counties may be cleaned before seeding time. The 10,000 bushels already signed will seed approximately 8,000 acres.

Approximately 375 soft red winter wheat growers attended meetings which the extension service of the agricultural college recently held to launch the wheat improvement program in Gallatin, White, Edwards, Wabash and Lawrence counties.

This territory was once recognized as producing some of the best quality soft winter wheat in the entire winter wheat belt. In recent years, however, the increasing amount of garlic, cockle, sheath and other weed seeds in the grain has lowered the quality and taxed growers with a heavy penalty in the form of price discount of from one to five cents a bushel.

It was also disclosed during the recent meetings that much of the soft winter wheat in southeastern Illinois is now infested with the serious disease, smut, or stinking smut. In some cases it is so serious that buyers are not making bids on the grain but are merely taking samples and offering to buy to sell the wheat for the owning farmer for what it will bring.

Farmers are being urged to have their seed wheat run through a fan mill under a heavy blast of air and then treated with one of chemical dust treatments as a means of combatting the smut.

The 10,000 bushels of seed wheat that already has been signed up for the cleaning service and any that comes in later will be run through special high powered fan mills equipped to take out practically all the cockle and oat seeds, shrunk wheat kernels and from 25 to 45 per cent of the garlic and wild onion culms.

As a further step in the wheat improvement program, growers in the five counties will be encouraged to raise improved varieties with seed obtained from neighboring farmers having superior stocks.

-M-

Short Peach Crop Does Not Eliminate Cover Crop Need

Although Illinois will market only about 300 tons of peaches this year as compared with a normal crop of some 5,000 tons, growers should not neglect the practice of supplying a cover crop this fall for soil improvement and erosion prevention purposes, says M. J. Dorsey, chief in pomology at the College of Agriculture, University of Illinois.

Where the soil has been cultivated around the trees, the fertility of the orchard is likely to suffer from soil erosion whether the present crop is large or small. Likewise, adding humus to the soil in the form of green manure is always a good way to improve the future productivity of the trees, points out Dorsey.

It is often surprising the amount of cover crop growth that can be produced between older trees during favorable seasons when the lower branches are not too close to the ground. The success of the cover crop will depend, of course, on the amount of rainfall following the seeding. Now year, when the seeding can be done several times the ground can be worked after a rain, crops will make as promising a start on crop as any.

## Position Of Soybeans Strengthened By U. of I. Tests

Experiments which the College of Agriculture, University of Illinois has conducted during the past year on the lower cost production of higher quality beef were concluded at the recent annual cattle feeders' meeting, with the best lot of steers returning 30 cents a bushel profit for the corn that was used. Approximately 700 farmers from Illinois and neighboring states attended the meeting to hear the results which Prof. H. F. Risk, head of the department of animal husbandry, and Prof. R. R. Shapp, his associate, had obtained in a series of eight experiments with 200 Texas yearling steers.

Outstanding in the results was the demonstrated merit of soybean oil, an Illinois-grown protein supplement, in comparison with the more common cottonseed meal for fattening beef cattle. Pasture studies which the college started several years ago also yielded striking results the time when farmers are putting more land back into pasture and grass than ever before.

Poor results which cattle feeders had obtained last year and in previous seasons may have given rise to the fear that soybean oil meal was to blame, but the experiments this year, coupled with those of previous seasons, indicate that the Illinois-grown supplement is equal to cottonseed meal for producing quality beef at low cost. The results further fortify the position of soybeans, which are now being grown on an increasing acreage as a result of the AAA programs and other crop shifts. Illinois is the leading soybean producing state.

The three best lots of cattle in the experiment were steers that had been fed soybean oil meal as the protein supplement to their rations. The top lot of steers, which paid returns at the rate of 30 cents a bushel for the corn that was eaten, was so outstanding that the appraisal committee of packer buyers and commission men called it "as good a lot of yearlings as you will see."

These steers were carried on bluegrass pasture from December 22 until April 17 and then moved to dry lots to finish out the feeding period of 220 days. During the entire feeding period their average daily feed consumption was 12.4 pounds of shelled corn, 1.8 pounds of soybean oil meal, 5 pounds of corn silage and 1.5 pounds of alfalfa hay a head. They were valued at \$8.50 a hundredweight in the lot on the college farm or \$9.25 on the Chicago market. They gained an average of 2.38 pounds a head a day for the 220 days on feed.

To note the outstanding mixture in the pasture studies which the college started several years ago has been one including 15 pounds of bromegrass an acre, 10 pounds of bluegrass, 7½ pounds of red top, and 5 pounds of white clover. Some volunteer sweet clover came up in the field. A test plot that was harvested in this pasture yielded at the rate of 5,120 pounds of feed reduced to a 15 per cent moisture basis, or more than 2½ tons an acre. Fifteen beef heifers pastured on the 10 acres for 56 days this spring averaged 2.48 pounds a head daily gain.

Strong Soil Will Save Wheat Crop From Chinch Bugs

Wheat production, which has returned Illinois farmers as much as 20 to 30 million dollars in recent, more normal years, need not be abandoned because of the heavy chinch bug infestation this year and the threat of damage in 1935, in the opinion of the State Natural History Survey and the agronomy department at the College of Agriculture, University of Illinois.

If wheat that is seeded this fall is put on the more productive soils and the season is favorable, it will yield fair to good crops even under heavy infestations, it is said. This is borne out by observations made at many points during chinch bug outbreaks in the past and from a check on many Illinois farms in recent weeks. Care should be taken, however, to have a well-prepared seed bed, to seed a variety adapted to the locality and to plant late enough to avoid the Hessian fly.

If winter wheat, spring wheat, rye and barley were entirely discontinued next year in any area of the state and all the small grain acreage planted to oats, the latter crop would be heavily infested. Should weather conditions prove favorable, the chinch bugs would destroy the oats. In many sections of Illinois this year the oats were just as heavily infested as the wheat fields.

For the coming season, however, it would seem a poor practice to sow winter wheat except on strong land. On work soils the crop is almost sure to be heavily infested and more or less damaged by the chinch bugs. Furthermore, if the chinch bug threat continues, it would be inadvisable to sow spring wheat or barley in areas where there is a heavy infestation, since these crops are especially susceptible to chinch bug attack.

In the northeastern part of the state, including Will, Kendall, Grundy, LaSalle and adjoining counties, the winter wheat during the past season was largely killed by the over-wintering bugs. This would not have occurred in a normal year with anything like an average spring rainfall. On the whole, in all other sections of the state the farmer planting winter wheat on strong ground has had far better returns from this acreage than from other small grains.

-14-

Drouth Reveals Terraces As Conservers Of Moisture

Record-breaking drouth such as has extended over a large portion of Illinois this summer has demonstrated a new benefit of terracing sloping farm land--that of conserving the limited amount of rainfall, points out E. W. Lehmann, head of the agricultural engineering department at the College of Agriculture, University of Illinois.

Observations made in Bond county, Illinois, in former years of deficient rainfall have revealed that terracing and contour farming improved corn yields as much as 15 bushels to the acre. Like investigations in other areas and states have also disclosed the water conservation value of terracing. Heretofore, many Illinois farmers have thought of terracing mainly as a method of preventing soil erosion, especially in seasons of heavy rainfall. Now, however, they are beginning to realize that these same terraces have a value equally as great in years when there is only a small amount of rain.

Where terraces are constructed or where planting is done on the contour, a large part of the rain is held where it falls. The water soaks into the ground where it builds up reserve supplies that help carry crops through periods of long dry spells. When too, the terraces catch and hold water as it runs off higher ground.

Reports from other states readily confirm the terrace observations made in Illinois. In some areas terraced land has held back and absorbed from 5 to 200 per cent more rain water than unterraced slopes.

Spreading Waste Straw Increases Corn Crop Returns

Whatever straw they have this year probably will be prized by most farmers, but any that might otherwise go to waste can be made to pay handsome returns by spreading it over land where sweet clover green manure crops are to be plowed down, it is reported by A. L. Lang, associate chief in soil experiment fields at the College of Agriculture, University of Illinois. If it were not for the drouth and chinch bugs, there probably would be thousands of tons of straw go to waste this year. Experiments have now proved that it has a high potential value if used on Illinois' million acres of sweet clover for soil improvement.

At the Dixon experiment field in Lee county operated by the U. of I. College of Agriculture, straw when applied to sweet clover ground improved the following corn yields from 73 to 91 bushels an acre, or a gain of nine bushels as an average for the last three years, explains Lang. Likewise at the Clayton field in Adams county, the growth of corn was improved when straw was spread over sweet clover, although no definite check on yields has been secured as yet.

Other studies at the Clayton test plots point to the fact that burning straw and stubble after the small grain crop has been harvested with a combine will completely destroy any young clover. Then too, it is found that burning straw on sweet clover lands tends to reduce the returns from the succeeding corn crop.

The improved returns from spreading straw over fields carrying a green manure crop may be accounted for by three physical and chemical reactions, says Lang. In the first place, the straw itself furnishes organic matter for the soil—a necessary ingredient to give the proper balance of moisture, temperature and plant food elements.

Furthermore, a heavy growth of green manure legume material when plowed down alone often releases an excess of nitrogen for the succeeding crop. Straw as a highly carbonaceous material extends the period over which the nitrogen may become available and thus prevents excess loss by leaching. This makes a better balance between soil supply and plant demands.

It is also believed that the straw may furnish the necessary available potash that often becomes deficient during the rapid-growing season of the corn plant, especially on high lime soils and on ground being heavily cropped with sweet clover. This is particularly true on the lighter-colored soils.

-M-

Illinois Elms Are Not Attacked By Dutch Elm Disease

Illinois elm trees are not dying this year because of the Dutch elm disease, notwithstanding widespread and alarming reports to the contrary, according to a statement issued at the College of Agriculture, University of Illinois, by L. R. Tekon, Botanist of the State Natural History Survey. Dr. Tekon, who has been directing an investigation of elm diseases in Illinois for the past four years, says that to date not a single case of Dutch elm disease has been located in the state.

Root and trunk infections by fungi such as *Kylaria* or the lack of sufficient water are probably responsible for the apparently dying condition of many elm trees in Illinois this summer. The prolonged drouth and the series of dry years have tended to remove moisture from the upper soil and to lower the water table beyond reach of the root systems. This condition is noted by the browning of foliage over the entire tree.

Sudden wilting and death of elms in the central at top is usually the result of attacks by one or the other of two fungi, *Verticillium* or *Cephalosporium*, both of which are relatively common parasites of the elm, explains Tekon. They produce symptoms which are like those of the Dutch elm disease.

## Illinois Has a Serious Winter Field Seed Shortage

Illinois farmers, who in the years 1931 to 1933 used approximately 100,000 bushels of corn seed, will this year require 100,000 bushels of same hay seed to plant 100,000 acres of hay. This is the largest amount of hay seed in the history of the state, and the largest amount of any one crop seed in the history of the College of Agriculture, University of Illinois.

Farmers should, therefore, estimate their future seed needs, and should take immediate steps to secure their seed. The shortage is not only in oats, clover, alfalfa, timothy, and winter wheat, but also in some areas seed corn.

The shortage of winter wheat in Illinois became apparent following the late fall rains in the northern and probable north in 37 counties in the northern two-thirds of the state, and the extension division of the U. of Ill. College of Agriculture.

As a result of the shortage, the supply of seed oats is extremely short in the north, reports J. E. Harkins, extension director at the college. The shortage is not only in oats, but also in winter wheat harvested this year, and in winter wheat planted this year. The shortage will not be but even with a good harvest. The shortage of winter wheat of the state have no reserve seed, and the winter wheat seed will have to be shipped in from other states. The shortage is not only in winter wheat, but also in winter wheat, particularly in winter wheat. Furthermore, several counties did not harvest enough corn this fall to plant this year's winter wheat.

The most critical conditions are now in the west and northeastern parts of the state, but in practically all counties in northern Illinois it is reported that rains and heavy frost in the past few days have been spotted. In some cases the winter wheat has not yet reached the crucial time and as a result the winter wheat will be killed. The winter wheat on both farms in the same area should be killed. When these spotted conditions exist, the winter wheat should be harvested as soon as having grain of seed quality, and the winter wheat should be stored immediately.

As a result of the shortage, the winter wheat is being made to locate reserve seed in the north and Illinois. The winter wheat for their 1935 spring planting will be located in the north and Illinois. The winter wheat may be found in certain areas in the north and Illinois. The winter wheat is less fortunate than Illinois.

As a result of the shortage, the winter wheat is being made to locate reserve seed in the north and Illinois. The winter wheat for their 1935 spring planting will be located in the north and Illinois. The winter wheat may be found in certain areas in the north and Illinois. The winter wheat is less fortunate than Illinois.

Save Save Corn Against Chinch Bug

In spite of the damage from chinch bugs and drought this summer, Illinois farmers will be able to save much of their corn crop by making it into silage, says W. B. Nevens, associate chief of dairy cattle feeding at the College of Agriculture, University of Illinois.

Immature corn that is drying up because of the lack of moisture and chinch bug injury will make a fair grade of silage, although its feeding value will not be quite equal to that made from more mature corn. Furthermore, chinch bugs do not seriously affect the palatability of silage.

To insure success in making silage from corn that is drying up, explains Nevens, the plant must have a moisture content of at least 65 percent, and best results are obtained when the corn contains 70 percent moisture. If it is less than 65 percent, water must be added.

To determine the moisture content of the corn, six or eight representative stalks should be cut into 1 to 1½-inch lengths. A three or four pound sample is then weighed out accurately and heated in an oven until it ceases to lose weight. This will usually require three to five hours at a temperature below that which will char paper. After the moisture has been driven out of the corn sample, it is reweighed.

The loss in weight of the sample, divided by the original weight before being heated and multiplied by 100 will give the percentage of moisture in the cornstalks. If the moisture is higher than 60 percent the corn will keep in the silo, provided other conditions are good. If the moisture content is 60 percent, 80 gallons, or 366 pounds, of water should be added to each ton of corn put in the silo. If the moisture content is 65 percent, then 120 gallons of water should be added to the silage. For each drop of 5 percent in the moisture of the corn being ensiled, an extra 40 gallons of water is added to each ton.

-1-

New Bulletin Is Aid To Illinois Farm Adjustments

With some 125,000 Illinois farmers adjusting their operations this year as cooperators in the government's AAA corn-hog and wheat programs, an interesting bulletin just issued by the College of Agriculture, University of Illinois, should prove unusually timely and helpful in making these changes.

Originally written in 1929 under the title of "Organizing the Corn Belt Farm for Profitable Production," the publication was revised this summer by H. C. M. Case, chief of the college's farm management division, and R. H. Wilson, associate chief, to bring it up to date in every respect. The practices, yields and incomes and expenses of hundreds of Illinois farms have been analyzed in determining the most profitable factors in farm management.

For example, a study of 67 farms in Woodford, McLean, Tazewell and Livingston counties revealed that during the five years of 1928 to 1932, the farm with the highest earnings made an average of 6.98 percent a year on an average investment of \$49,247. This income was the result of years of definite effort by the operator to put the farm on an efficient production basis.

The least profitable farm in the group, however, lacked \$63, or 1.28 percent, of making any return on the investment after operating expenses were paid. This difference in the two farms amounts to 8.26 percent, or \$4,442 a year on an investment of \$53,781, which was the average investment of all the farms in the study.

That better earnings are realized year after year by some farms in a community than other farms operated under the same natural and economic conditions, is a matter of common observation, point out the authors. But the causes for these differences in net incomes are not so generally understood, and it was for this reason that the studies were made and the bulletin published. Copies of Bulletin 329, "Organizing the Corn Belt Farm for Profitable Production," may be obtained from county farm advisers or by writing direct to the College of Agriculture, University of Illinois, Urbana.

Can Sow Alfalfa, Red Clover Now For 1934 Crop

With most of the 1934 seedings of timothy killed out by the drought, Illinois farmers who have not already taken steps to replace this loss by summer seedings of alfalfa or red clover, should do so immediately, suggests J. J. Hackleman, chief in crops extension at the College of Agriculture, University of Illinois.

Experiments have shown that for best results alfalfa should be seeded during the latter part of July or early August, but this year it was too dry over much of the state to get a good stand at that time. However, when recent rains have supplied sufficient moisture and if favored by a comparatively late fall, there is still a good chance for alfalfa sown immediately to come through the winter and make a crop next summer.

That alfalfa deserves its title as the premier hay plant in Illinois is attested by the way it came through the hot, dry weather in much of the state the last two years. Although it represents only 16 per cent of the same hay acreage of the state, it will produce approximately 4 per cent of all hay harvested in Illinois in 1934.

However, when seeding alfalfa for 1934 harvest, Illinois farmers should bear in mind certain fundamental principles in the production of this legume, points out Hackleman.

First, the soil on which it is to be grown should be relatively sweet; it should test medium to strong in available phosphorus, and should be well drained.

Likewise, the seed bed should be well pulverized on the surface and compact in the subsurface. A loose, cloddy soil makes a poor seed bed for any hay seeding.

As another consideration, if possible, the grower should use a strain of seed that is comparatively winter hardy. Northern and northwestern grown seed is usually considered more hardy than that produced in the west and southwest. But if unable to obtain these hardy types, that from the central west is generally hardy enough to withstand at least two or three winters. Of course, if the field has not produced a good crop of alfalfa or sweet clover in the past, the seed should be inoculated.

If these same precautions are taken, August-sown red clover should also come through the winter and make a good hay crop next summer, he is sure.

Silage Loss Often Saved By Early Repairs

Repair parts for ensilage cutters that will fill Illinois' 20,000 silos may be more difficult to obtain this fall, particularly for the older models that are being dug out of fence corners for the first time in several seasons, says R. H. Ford, agricultural engineer at the College of Agriculture, University of Illinois.

Manufacturers will, of course, make every effort to supply prompt repair service for any machine in use, but farmers should not run a needless risk by waiting until the last minute to order a part that may have to be made at the factory.

The poor condition of the corn as a result of the extreme drought and heavy chinch bug infestation, together with the fact that many fields may suffer additional damage if left too long, makes it more important than ever to have the silo-filling equipment ready on time.

An experience of an Illinois farmer several years ago might prove disastrous, if repeated this fall. He failed to examine his cutter until the night before the crew was to fill his silo. Several broken parts were discovered and it was two weeks before the machine was repaired and filling could be started.

The cost of the parts required for the machine and the labor involved in making the repairs were the same as if the work had been completed a month earlier, yet the delay caused a material decrease in the value of each ton of silage made.

### Illinois Produces Most of World's Redtop Seed

While most people think of bluegrass as the major component of all lawns and pastures, the annual production and consumption of redtop seed in the United States has been nearly equal to that of the famed Kentucky product.

Furthermore, practically 75 per cent of the world's supply of redtop seed and 95 per cent of the total redtop seed in this country is produced in a dozen counties in southern Illinois.

These and other interesting facts are disclosed in bulletin just issued by the College of Agriculture, University of Illinois, under the title of "Production and Marketing of Redtop." Four specialists cooperated in preparing this attractive publication, the authors being W. L. Eurlison, head of the department of agronomy; C. L. Stewart and R. C. Ross, of the department of agricultural economics, and O. L. Whalin, formerly in the department of agricultural economics.

The concentration of redtop seed production in Marion, Wayne, Clay, Richland, Edwards, Jasper, Fayette, Clinton, Jefferson, White, Wabash and Lawrence counties—all in southern Illinois—has been due to a combination of economic factors, favorable climate and soils not so well adapted to other crops.

During the 12-year period of 1924-1935 approximately 20,000 acres of redtop were harvested annually for seed, with average yields of 54 pounds to the acre. In the past three years, however, the threshing of redtop has declined largely due to the loss in market value. Prices of redtop seed fell to the low of 3.4 cents a pound in 1932 as compared to the high market of 20 cents a pound in 1915 and 1925, and the average of 11.3 cents during 1915-1931.

Copies of Bulletin 404, "Production and Marketing of Redtop," may be obtained from county farm advisers or by writing direct to the College of Agriculture, University of Illinois, Urbana.

-X-

### One Good Cow Is As Profitable As 423 Culls

Many Illinois dairymen are, figuratively, milking 423 cows of low producing ability when one good producer would give them the same profit above feed costs, if records of individual cows on test in the Ogle County Dairy Herd Improvement Association can be considered as typical, says J. G. Cash, dairy extension specialist at the College of Agriculture, University of Illinois.

This is revealed in a summary of production figures kept by Ogle county dairymen which shows that there were 20 cows in the association last year that averaged only 167 pounds of butterfat and returned an average of only 13 cents a head above their feed costs. Such fat production is equivalent to the average for all cows in the United States. On the other hand, there were 12 cows on test that produced an average of 576.3 pounds of fat during the year and returned \$76.14 a head above feed costs. Thus it would have taken 423 cows like those in the low-producing group to return as much profit above feed costs as one cow in the high-producing group.

Furthermore, the low-producing cows, and there are thousands of them on farms in Illinois, are daily adding to the burdensome milk surplus. They are steadily breaking down the market prices of both milk and butterfat without paying their owners even for the labor and feed they require.

Examples like this one, points out Cash, illustrate the value of cow-testing work to the dairy industry. Only by being members of a dairy herd improvement association can farmers discover which of their cows are returning only a few cents a year above feed costs and which ones may be netting as much as \$76.14 a head.

## Mad-Dog Disease and Rabies in Illinois

A mad-dog bite probably from a German shepherd dog of "Cockfield" and "Log" breeds, owned by a farmer in a small town in the north-western part of Illinois, was particularly fatal to a woman and her child. The woman, Mrs. Dr. Robert Grant, died in a hospital in Chicago on August 10th. The child, a boy, died in a hospital in Chicago on August 11th. The case is being investigated by the Illinois State Board of Health, Chicago, Illinois.

In fact, rabies has been reported in Illinois in various places during the month of January and February in the past. In 1913, a case of rabies was reported in the State of Illinois, near the town of Chicago, Illinois. The case was reported to the Illinois State Board of Health, Chicago, Illinois. The case was reported to the Illinois State Board of Health, Chicago, Illinois. The case was reported to the Illinois State Board of Health, Chicago, Illinois.

Avoid strange dogs or dogs showing any signs of illness.

Isolate all ownerless and stray dogs, but do not kill rabid suspects until definite diagnosis has been made.

Isolate all dog suspects and notify the owner or a local veterinarian as quickly as possible and consult the local health officer.

Is bitten by a dog, seek medical attention immediately. The Pasteur treatment is necessary and prophylactic.

The first and best remedy to prevent the development of rabies virus.

If these preventive measures are followed by all people, Illinois would not experience this fatal rabies disease so often as it does in this State. Says Dr. Grant:

### One Acre Of Rye Will Solve Spring Pig Troubles

An acre of rye sown between the first and twentieth of September will solve the major troubles Illinois farmers have in raising early spring pigs, in the opinion of W. E. Cornell, chief in swine husbandry at the College of Agriculture, University of Illinois.

The chief difficulty that many produce as they in handling early pigs comes from the fact that no quarters are, from the barnyard and other animals are available for the pigs soon after they arrive in February or early March. As a result parasites and filth-borne infections such as necrotic enteritis attack the pigs so early that they have little chance of attaining rapid, profitable growth.

If a clean pasture is provided in a field that has never been grazed in recent years, the sow and her litter can be handled on this "new" ground where the pigs can grow without the handicap of worms and disease germs.

On the University of Illinois Farm near Urbana, rye sown in early fall will usually develop satisfactorily and be ready to graze by the first of the following March. The fall growth provides early grazing, while the early spring growth will be ready to supply forage after the soil beneath has been eaten. Handled in this manner, an acre of rye has provided more food for a head of pigs and their mothers from the time the pigs begin to eat until they are weaned.

It is customary at the university farm to stock the acre at the rate of 16 sows and litters to the acre at first, but by the last of March the rye will support 16 to 18 sows and litters to the acre.

The rye can be depended on to provide cover until the middle or last of April, at which time the alfalfa or clover pasture is usually ready for hog grazing. If moisture conditions are right, the acre devoted to rye can then be plowed and planted to corn, or in an unfavorable season it can usually be put in shape in time to plant to soybeans or silage corn.

-11-

### Cattle Not Injured By Chinch Bug Infected Silage

Prevalent as chinch bug have been this winter in some 70 to 80 Illinois counties, the insects will not affect the quality of the silage made from infected corn, according to F. P. Flint, chief entomologist of the State Natural History Survey and the College of Agriculture, University of Illinois.

Silage made from heavily-infected corn stalks may carry a strong chinch-bug odor for three or four weeks, but this will eventually disappear, it is said.

During former chinch bug attacks, particularly the outbreaks in southwestern Illinois in 1910-1911, a large number of silos were filled with corn infected with the insects. In many cases the corn was so covered with bugs that the silage had the disagreeable chinch-bug odor, making it almost impossible to remain in the silos for more than a short time while they were being filled. After the silage had settled for three or four weeks, practically all of the chinch-bug odor passed away, the remaining odor being the same as ordinary silage.

There was no question but what this silage had a lower nutritive value than silage made from corn that had not been injured by chinch bugs, but it was readily eaten by the cattle during the following winter with no reported injurious effects.

"So far as our observations go," says Flint, "there is no danger of feeding such silage and so far as we have been able to learn, no injurious effects have occurred from feeding such material to either dairy or beef cattle. It is, of course, possible that some injury might occur, but this seems improbable in light of the past experiences of many Illinois farmers."

-11-

Machine Cutting Both Silage And Hay Most Efficient

There never has been a year when it has been so generally admitted that Illinois farmers make the best use of their hay and silage as in the past. For this reason thousands of farmers are turning to both the right and the left in order to conserve their strength and energy by doing a comparatively small job.

This increased use of silage is likely to bring about greater demand for silage cutters than in any year in all parts of the state, according to R. H. R. A., agricultural engineer at the College of Agriculture, University of Illinois.

While most farmers, however, plan to harvest at least a part of their corn in the tops of silage, hope to use their own silage cutters, or to hire cutters from their neighbors, many may be forced to purchase new machines this fall, it is believed. To such farmers, R. H. R. A. has a word to say in the purchase of a machine that will cut and chop hay and silage alike.

Ordinary silage cutters will not do what a hay and silage chopper will, but most hay choppers will cut and chop silage. The main objection to the hay chopper, the farmer will hold, is that it requires more fuel and more of the work required in operating the machine. In fact, one of the main objections to such machines in the past has been that some of them are difficult to run and operate and their usefulness is thereby limited to a few seasons of use. The newer cutter that will chop silage will also chop hay and thus help to bring about the elimination of this criticism. Farmers on the whole are turning away from the old in Illinois and other states in favor of the new and better, a superior hay in the chopped form.

Evening is said that it is better to cut the hay and chop it to chop hay before using it and, it is said to be a matter of convenience to purchase a machine that will serve both in hay-chopping and silage-chopping, and to buy a

45

Best Hay For Cattle Is One That Is

With the possibility of another black blizzard in 1917 and the ever-present danger of winter-killing, Illinois farmers should plant only those varieties of wheat this fall that have proved the best in their respective parts of the state, says G. H. Dwyer, associate chief in crop production at the College of Agriculture, University of Illinois.

When resistant varieties are planted on strong ground, observations indicate that fair wheat yields can be obtained in spite of a bad winter.

In the central part of the state, where the Illinois Progress wheat this year again demonstrated its ability to yield well. The variety is a soft wheat with considerable winter hardiness, superior grain quality and high yielding capacity on fertile soils. Wheat of the Paris type has been considered as adapted to central Illinois and a variety that can compete with the Paris type on the central Illinois Progress wheat has done this for eight years in its own central Illinois.

At the experiment field near De Kalb in central Illinois, five wheat varieties stand out in front with better yields of high yielding wheat than in the past years. They include Kansas, Illinois Selection 111, Illinois 1, Turkey and Wisconsin Redigree. These are all selections from the Paris type wheat in which the best of the parents.

On the Atlantic experiment field in southern Illinois, the best winter wheat are the best adapted, and have the following varieties included: Fayette, W. No. 1, Illinois Selection 111, Michigan Amber, R. H. 1 and Fulbright. Of these, Illinois Selection 111 is the only variety not in the soft wheat class.

## Corn-Hog Check To Illinois Exceeds \$1,000,000 Mark

Buying power of Illinois farmers has been increased by more than a million dollars in the past year as a result of AAA corn-hog benefit payments, it is estimated by the College of Agriculture, University of Illinois. Furthermore, within the next few weeks the total in benefit checks to the 14,000 corn-hog contract signers in this state would reach nearly \$17,000,000.

The first checks to be received by Illinois farmers cooperating in the government's corn-hog adjustment program began to arrive the last of July and by the middle of August the benefit payments aggregated \$17,710,000. Since then checks have been distributed so rapidly that any up-to-date total cannot be determined. It is believed, however, that the total amount received by Illinois farmers prior to September 1 will be well over the million dollar mark.

Present reports, it is pointed out, represent only about 6 per cent of the nearly \$17,000,000 to be received as the first benefit payments to corn-hog contract signers in Illinois, most of which will be paid by early October. Approximately \$3,000,000 will also be received by Illinois participants after November 15, when the second benefit check becomes payable. A third installment, amounting to about \$3,000,000, less local administrative expenses, will be sent to cooperators in this state after February 15, 1937.

According to the latest available figures, Ford county leads the list in benefit payments received prior to August 17 with a total of \$1,777. Henderson county ranks second with checks aggregating \$475,000, while other counties that have received more than \$100,000 include: Greene, \$1,000,000; Fayette, \$350,015; DeWitt, \$30,236; Will, \$2,000,000; Logan, \$7,000; Clark, \$1,100,000; Boone, \$4,000; Macon, \$22,884; and Cook, \$1,000.

Corn-hog checks are being mailed out of Washington at the rate of nearly two million dollars a day to contract signers in all of the 48 states, it is said. By August 14, total disbursements by the AAA corn-hog section approximated \$45,000,000, or about a third of the total first installments of some \$133,000,000 to be distributed to signers of the 1934 adjustment contract.

By mid-August Iowa farmers had received \$2,142,400 to head the list of states in total benefit money so far, while payments to other mid-western states included: Missouri, \$4,347,567; Ohio, \$4,040,070; Nebraska, \$3,796,950; Minnesota, \$2,775,426; Indiana, \$1,740,000; and Wisconsin, \$1,000,000.

-M-

Smut In Wheat Reduced By Either Of Two Processes

In their efforts to protect their 1935 wheat crop from serious injury by stinking smut, or bunt disease, Illinois farmers have a choice of two effective chemical seed treatments--copper carbonate or Ceresan--either of which will be a profitable precaution this fall, says Benjamin Koehler, crop pathologist at the College of Agriculture, University of Illinois.

The copper carbonate may be purchased in either full strength or diluted forms, but for Illinois conditions the latter containing 12 to 20 per cent copper has been found satisfactory. If the grain is not discolored and does not have an odor, two ounces of copper carbonate to each bushel of seed is recommended. However, if the wheat is discolored and has a foul, smutty odor, then  $\frac{1}{2}$  to 3 ounces should be used.

If Ceresan is used, the directions accompanying the compound should be followed. The materials and seed are mixed together in a tight mixing machine, similar to that used in treating seed corn, until all kernels have been covered by the powdered chemical.

When comparing copper carbonate and Ceresan, it is found that each has certain advantages over the other. In the matter of dosage, there is no danger of "burning" the grain by an overdose of copper carbonate, but using more than one-half ounce of Ceresan to the bushel is injurious. Furthermore, wheat treated with copper carbonate may be stored in a dry place indefinitely without deterioration, while Ceresan causes noticeable damage to the wheat grain after a week's time.

Ceresan, however, has the advantage of not clogging the cylinders of the wheat drill as often happens when wheat treated with copper carbonate is allowed to remain in the drill overnight in damp weather. Then too, Ceresan does not require as thorough an application as copper carbonate because it acts to some extent as a gas as well as a contact disinfectant.

-1-

Cow Families Responsible For Best Dairy Herds

One or two foundation cows are often responsible for many of the most outstanding of the 1,006 herds in Illinois dairy improvement associations at the present time, according to C. S. Rhode, chief in dairy husbandry extension at the College of Agriculture, University of Illinois.

These cows, originally selected for their efficient milk and butterfat production, have become the dams of what are known as "cow families." Their daughters, granddaughters and great-granddaughters have proved as efficient producers as the foundation cows and have been retained in the herds from generation to generation until now they make up the major portion of the better dairy herds of the state. Gradually they are spreading the highly desirable influence of the original foundation cows.

Too much cannot be said regarding the importance of the herd sire, points out Rhode, but at the same time it should be recognized that the dam contributes as much to the offspring as does the sire. The bull, if he has the ability to transmit high productivity to his daughters, will steadily increase the efficiency of the herd. However, if high-producing dams are also used in the breeding program, the progress is much more rapid. The wise selection of both sires and dams of heifers for herd replacement offers a great opportunity for advancement for the average dairyman.

An example of an outstanding cow family is found in a herd in Kane county dairy improvement association No. 2. Pearl Eunice DeKol Beets is the foundation cow and during five consecutive lactation periods she produced an average of 614.4 pounds of butterfat annually. Of her daughters, one produced 567.8 pounds of fat in a year's time, while two others have equivalent records. One granddaughter produced 577.7 pounds of fat as a five-year-old, and another 540.7 pounds. Three great-granddaughters have records that are equally as good, all of which contribute to the success of the herd.

-1-

### How Is Time To Begin Controlling Poultry Pests

Before Illinois farmers begin housing their more than 20 million chickens for fall and winter production, it will be decidedly profitable to thoroughly clean and treat the poultry buildings for lice, mites and other parasitic insects, suggests M. D. Farrar, entomologist of the State Natural History Survey.

Unless effective control measures are taken at this time, flocks often become so heavily infested with these insect pests that they become unthrifty, egg production declines and thousands of dollars in poultry profits are lost by producers.

Some of the more economical and effective oils to control mites, bed bugs and fleas in the poultry house are creosote, kerosene and waste crank case oil, applied with a brush or emulsified with soap and water and sprayed on the inside of the building. Dormant tree spray emulsions mixed at the rate of four or five gallons in 100 gallons of water are also efficient poultry insect destroyers, points out Farrar in a report to the College of Agriculture, University of Illinois.

Poultry lice spend their entire lives on the birds and thus must be controlled by treating the fowls. For this a good grade of sodium fluoride is economical. Each bird is dusted individually by applying a pinch of sodium fluoride under each wing and around the vent, ruffling the feathers to allow the powder to sift into the plumage, or the birds may be dipped in a solution of one ounce of sodium fluoride in one gallon of water.

Where it is impractical to handle each bird, painting the roosts with 40-per-cent nicotine sulphate is recommended. A line of the disinfectant about one-fourth inch wide is applied along the roosts just before the birds retire. The nicotine fumes filter through the birds' feathers, killing the lice. This treatment should be repeated in 10 to 14 days as it does not kill the eggs. All lime or white-wash should be removed from the roost before the nicotine sulphate is applied.

-M-

### New Circular To Aid Farmers Cut Tractor Expense

Whether the owners of approximately 70,000 tractors on Illinois farms derive the maximum service from their machines depends largely on the care exercised in their operation and maintenance, points out E. I. Showl, author of a circular on "Tractor Repair and Maintenance", just issued by the College of Agriculture, University of Illinois.

As a result of proper care and maintenance, a general-purpose tractor at the College of Agriculture recently completed nine and a half years of service at an average repair cost of only \$59.37 a year. During that time it completed nearly 6,000 hours of general farm work, and it was not until after the first five and a half years that any major repairs were necessary. The tractor is still good for several years of work and will not need to be junked until the hour-cost of operation exceeds that of the newer and better tractors now being made.

It is to aid Illinois tractor owners in holding down maintenance costs and to help them do some of their own repair work that the new circular has been prepared. The publication includes 48 pages of instructions dealing with common tractor troubles and their remedy, such as the grinding of valves, adjusting the carburetor, checking the ignition parts, repair of the cooling system, power transmission problems, lubrication suggestions and a discussion of types of tractor fuels. Well illustrated and thoroughly indexed, the circular provides a practical handbook for tractor owners. Copies of Circular 425, "Tractor Repair and Maintenance", may be obtained from county farm advisers or by writing direct to the College of Agriculture, University of Illinois.

## Illinois Farmers Can Have Their Own Shelter Belts

Shelter belts for certain sections of Illinois would be just as beneficial to individual farmers, and to the state, as the newly approved 100-mile-wide federal shelter belt will be to the country as a whole, says L. H. Meyer, extension forester of the College of Agriculture, University of Illinois.

In the national project, the belt of trees will extend from the Canadian border down through North Dakota, South Dakota, Nebraska, Kansas and into the Texas panhandle and Oklahoma. But the thing that will do for the entire middle west could be done on a smaller scale on individual farms throughout Illinois and the beneficial results could be felt throughout the entire state.

A shelter belt around the farm home, its lot ground on either farmstead, points out Meyer, will do it in much the same desirable way in which to live, as the presence of the belt of trees will break the velocity of the wind both in winter and summer. In the winter months, slowing of the velocity of the wind will have a cooling effect on the surrounding territory. The presence of the trees will increase the humidity of the air, and in the trees, the trees can be planted so as to aid in the control of soil erosion.

In the winter time, the line of trees will equal a number of beneficial effects. A wind of the biting, winter type will be lessened in force and be less harmful to the animals and the buildings. The farm and other buildings will be more livable for the livestock.

Establishing a shelter belt is neither difficult nor an expensive task, when the proper methods are used and could be required for the average Illinois farm, says the claim. With a few such shelter belts requiring a large area of land that could easily be used as better cropland on other parts of it. The land that is required and the expense involved would be more than offset by the added value to the land and the improvement in the living conditions.

Much of the middle west has suffered severely from the prolonged drought this year. The economic and social consequences are serious, it is pointed out. The dust storm which blanketed the country from the Dakota to the Atlantic seaboard was a striking reminder of the incipient desert conditions of the Great Plains.

Man cannot change all the forces of weather, but he can modify his own surroundings. He can improve the effects of the weather. If the surface velocity of the wind over a wide area can be broken and decreased even slightly, soil will be held in place, the surface of the soil will be conserved, and havens of shelter will be created for man, beast and bird.

The development of shelter belts both on large and small scales is not entirely new or untried activity, it is explained. On the contrary it is based upon the long-time experience of several European countries, particularly Italy, Hungary and Russia. In these countries where shelter belts have been used over a period of years and on an extensive scale, farming enterprises have been stabilized and have succeeded even in the worst seasons when many other areas have suffered serious losses to their crops through adverse weather conditions, says federal authorities.

New U. of I. Circular Pictures Dairy Cattle Types

Dairyman of this state who own more than 1,111,000 milk cows and heifers and who buy, sell and trade thousands of head annually, will find considerable assistance for their transactions in a new circular, "Selecting Dairy Cattle," just published by the College of Agriculture, University of Illinois.

Many thousands of cattle are bought and sold every year for dairy purposes merely upon the evidence which their external appearance gives of their ability to produce milk, points out the circular. In such dealings, the buyer who knows the characteristics of a good dairy cow has a distinct advantage, while the untrained buyer may be sadly disappointed in his purchase, once he has had an opportunity to test the animal's productive ability.

It is to assist in lessening the number of these disappointments and to aid in raising the standard of dairy cows in this state that the new publication has been prepared by W. F. Meyers and A. F. Kublan, of the U. of I. dairy department. The circular contains some 30 photographs and drawings which portray many of the desirable and undesirable characteristics to be looked for in dairy cattle. Jerseys, Holsteins, Guernseys, Ayrshires and Brown Swiss are among the breeds pictured in the booklet, with separate sections devoted to the selection of bulls, heifers and mature cows. The publication makes a practical handbook for teachers and students in vocational agriculture classes as well as for leaders and members of 4-H dairy clubs.

"Knowledge of the characteristics of good type in dairy cattle is important, not only to the buyer of new female stock, but also to herd owners who wish to raise heifers from their own best cows to replace some no longer useful or profitable," explain the authors. "If the quality of the herd is to be constantly improved, ability to judge good type is essential." Copies of Circular 40, "Selecting Dairy Cattle," may be obtained from a county farm adviser or by writing direct to the College of Agriculture, University of Illinois, Urbana.

-11-

Local Sales Cut Costs In Year Of Light Apple Crop

With one of the smallest Illinois apple crops in the past 10 years, growers who are fortunate enough to have trees bearing this fall will have an excellent opportunity to dispose of their apples through local markets at a minimum expense, according to J. W. Lloyd, chief in fruit and vegetable marketing at the College of Agriculture, University of Illinois.

The state's 1934 apple crop has been estimated at approximately 1,54,000 bushels or less than a third of the average annual production during the past 10 years. Only in 1931 and in 1932 were the apple crops less than is estimated for this year. For the United States, however, it is believed that the total apple crop will amount to about two-thirds of the average for the past decade.

In seasons of a light crop like the present, the local demand for apples may well be given first attention by orchardists. From the standpoint of the grower, marketing locally has several advantages, Lloyd explains. The cost for packaging and packing is much reduced, since the local purchaser usually brings his own packages and no packing is necessary. There are no freight bills nor brokerage charges to be deducted from the selling price, because the local buyer provides the transportation and business is transacted directly between producer and consumer. Handled in this way, a short apple crop is likely to net the grower a greater return than if the fruit were shipped to the large city markets.

To market apples successfully by this method, it is necessary for the orchardist to let the people of his vicinity know that a few apples are on hand they will be available. Reading notices in local papers usually serve this purpose adequately.

-12-

### Cleaning Hints For Rugs And Furniture Explained

With fall house cleaning time just around the corner, homemakers everywhere are worrying about how they can brighten up the appearance of the living room rug or remove that ugly spot on the upholstered chair or velvet davenport.

To make this part of house cleaning as easy and as effective as possible, Miss Isabelle Hitchcock, home furnishings specialist at the College of Agriculture, University of Illinois, makes several timely suggestions.

For cleaning rugs or cloth upholstered furniture that are not badly soiled, mild soap flakes should be dissolved in warm water and stirred with an egg beater until there is a thick, dry lather, explains Miss Hitchcock. The suds should then be tested on an inconspicuous place to make sure that the fabric will not fade. A stiff bristle brush should be used, applying the lather only to a small section of the rug or furniture covering at a time and always working in a rotary motion until the lather is soiled. The soap should then be wiped up with a clean cloth or sponge wrung dry from lukewarm water. A generous application of suds will prevent unswollen cleaning, but care must be taken to use only the dry lather so that the stuffing in the furniture will not become damp. Soiled furniture coverings such as terylene, denim, rep or frieze which are fast in color may be freshened in the same manner.

Grease spots or oil stains may be removed from upholstered furniture and rugs by using naphtha, chloroform, carbon tetrachloride or a detergent. When using naphtha or chloroform, the furniture should be moved into the open air. Either of the liquids can then be applied to the stain, working from the outer edge to the center and allowing it to soak in well. A piece of blotting paper is then placed over the stain and pressed with a slightly warm iron. If carbon tetrachloride is used, the spot should be sponged thoroughly with a cloth saturated in the solution, using another clean cloth to absorb the soiled cleaning fluid before it evaporates. All rubbing should be done with the nap.

### Fuel Expenses Can Be Saved By Small Home Repairs

Illinois farm families who wish to save money on the annual coal bill and at the same time enjoy warm comfort during the cold winter months should begin now to make certain needed repairs about the home, suggests W. G. Foster, rural architecture specialist at the College of Agriculture, University of Illinois.

Loose-fitting doors, rattling windows, cracks under the baseboard, in floors and plaster produce drafts that reduce the comfort of the home, cause grief to the occupants and add money to the coal man's purse. All of these are little things which should be fixed before winter comes and, fortunately, require very little material or expense. In most cases, a small amount of time and labor are the chief requirements, points out Foster.

Twenty feet of bronze weather stripping and 30 minutes time will make the door fit like new. A check of the sash and reseating of stops will improve the windows and stop the leaks there. Plaster repairs not only keep the cold air out of the house but improve the appearance of the home. Reseating of the corner strip or shoe mold will eliminate many floor drafts, wall gun corking may be purchased from the building materials dealer and applied with a putty knife or the screw-type grease gun.

All of these minor repairs may be done by the handy man in a hour's time at a surprising low cost. The saving in fuel alone will pay for the material several times over each year, while the extra comfort and saving in health give added incentive to make the repairs. Count the cost of wasted fuel and compare it with the actual cost of repairs, and then you will wonder why the little tasks were not done long ago, says Foster.

## Control of Corn-How Production in Illinois

First of the series of public meetings to discuss the present economic situation of corn-how production in Illinois will be held in the near future. The question of control of corn-how production will be discussed at a series of conferences of officials held from September 1 to 15, 1934.

Farm advisers and members of county committees have been called to attend the public meetings which will be held in the following counties: North-west, College of Agriculture, University of Illinois.

The schedule of the meetings, by county, is as follows: Northeast, September 1 at Havana; Northwest, September 2 at De Kalb; West, September 26 at Macomb; East, September 27 at Fulton; Central, September 28 at Macomb; West-southwest, September 29 at Millville; Southwest, September 30 at Pinckneyville; Southeast, September 31 at Ridgely; and the next day, September 26 at Birmingham.

All of the public meetings will be held in line with recommendations made by the committee on corn-how production, Indiana, Ind., and which are being handled by the Illinois Live Stock Association, Chicago, Kentucky and Tennessee. The following are the official Illinois representatives: Dean Herbert W. Mumford, of the U. S. Bureau of Animal Industry, Prof. J. C. Stiles, state leader of farm advisers, and F. J. Kinloch, extension director.

The following are the state committee members on corn-how production: also attended, including E. C. Ewert, secretary, of the Illinois State Grange; J. E. Fullerton, Jacksonville, and Ray Miller of the Illinois Live Stock Association.

After the 1934 corn-how contract terminates there will be no control of corn-how production unless some new plan is developed.

In the meantime, the officials believe, the corn-how producers will get the best results if they should discuss the situation with regard to feed and fertilizer and to see if it is possible to restrict or not the use of fertilizer program in the corn-how kind of a program that shall be.

The public meetings will be in the nature of training schools for the county advisers. After their return they will assist in holding county meetings to which all community chairman of the corn-how production control association will be called and at which they will be trained.

One of the main items will then be organized for holding a series of community meetings throughout each county with the idea of reaching all corn-how producers. This series of meetings will be concluded in time for the Illinois corn-how to be sent to Washington before October 15.

No Shortage Of Seed Corn Liable In Illinois In 1935

Unless it is fortunate farmers in some other state, Illinois corn growers should have plenty of seed available from the state's 1934 crop for planting a normal crop of around eight million acres next season, in the opinion of J. C. Hackleman, chief in crops extension at the College of Agriculture, University of Illinois.

Hard hit as it is, the state's 1934 corn crop will amount up to the needs for next year in farmers pick instead of the right kind of seed at the proper time and store it safely during the winter, Hackleman said.

In case there sufficient gold reserves will not be available for seed, 1937 cribbed corn can be used, but it is less desirable for seed purposes than good quality 1934 corn, it is said.

Following a trip through 27 northern and central Illinois counties, Hackleman reported that whole counties in one section and several parts of the other counties of the state may have an excess of corn seed for this fall. Farmers in other counties may have to import from 2,500 to 6,000 bushels each of seed corn from the more fortunate counties.

A shortage of seed from 1934 corn will be prevented to all extents, if farmers in the more favored areas will select plenty of seed this fall so that it may be made available to growers in the less fortunate areas, it is believed. It is recognized that the situation is so serious that it will be necessary for thousands of farmers to use old corn, but the number of such cases can be reduced if Illinois farmers who have good quality corn will accept their responsibility and select and store surplus of seed this fall, Hackleman said.

When selecting seed corn, it is best to pick only those ears that are located on plants that are well branched by the roots and are of main crop. The stem and parts of the leaves should be green while the husks have turned a straw color. Furthermore, the plant from which seed corn is selected should be free of smut and the ear should be supported by a sturdy, well-developed stalk. The husks should cover the ear well and the ear itself should not be unusually large in circumference as such ears dry slowly. Ears showing mold or insect injury should be discarded.

Farm Account Round-Up To Be Held In Ottawa, Sept. 27

H. E. Wilson, assistant secretary of the United States Department of Agriculture, is scheduled to be the headline speaker when farmers from some 40 northern Illinois counties gather for the farm bureau-farm management service round-up to be held at Ottawa, September 27, it has been announced by the College of Agriculture, University of Illinois. The meeting will be held in the Ottawa High School starting at 9:45 a.m.

How farmers who are keeping records in the service have approved their returns and put their business on a better basis in the face of conditions prevailing during the past several years will be discussed by representatives of the farm management division of the agricultural college. Approximately 150 farmers in Grundy, DeKalb, Marshall and Putnam counties are cooperating with the college in their present farm advisers in keeping records in the service.

The round-up is a tri-annual event, the first having been held at Morris in 1928 and the second at Bloomington in 1931. All farm advisers and farmers in northern Illinois who have been cooperating in record-keeping projects as well as others interested in farm management records have been invited to attend the meeting.

-12-

Feed Crisis Fattens Trend On Shroed Buying Of Cattle

Illinois farmers, who have been buying an average of more than 210,000 stocker and feeder cattle annually during the past several years, will have to be unusually shrewd in their buying this fall if they are to avoid disappointing results, in the opinion of Fred R. R. Saegge, assistant chief in beef cattle husbandry at the College of Agriculture, University of Illinois.

The critical feed situation will make it necessary to buy feeders on a different basis than has been the case for the past several years if the venture is to be a success, he pointed out. Only farmers with plenty of corn will be in a position to feed calves successfully, while farmers with limited supplies of grain will be wise to confine their purchases to yearlings and two-year-old cattle, he believes.

It seldom pays, and certainly not this year, to buy cattle because they "look like a bargain," with little or no thought as to whether or not they are adapted to the feed supplies and shelter equipment available for them at their new homes, it was pointed out.

Because of the shortage of grain and the low quality of available roughage, most farmers are not in a position to feed calves successfully. However, the comparatively few farmers who are fortunate enough to have an adequate amount of choice feed on hand will make relatively good profits from feeding calves, Saegge believes. This seems likely because of a probable scarcity of choice, light-weight slaughter steers next summer and fall.

Farmers with limited supplies of grain will do better to confine their purchases to yearlings and two-year-olds, since animals of these ages are well suited to utilize coarse feeds such as shock corn, soybean hay and corn silage. Furthermore, current market prices for both slaughter and feeder steers are favorable to the purchase of older and heavier cattle.

-M-

Subsoil First To Lose Fertility, U. I. Tests Show

Contrary to popular opinion, the subsoils of Illinois farms lose their fertility first and more rapidly from continued cropping than do the surface soils, it is revealed by recent studies made at the College of Agriculture, University of Illinois.

Heretofore, it has been generally believed that the top seven inches of soil was the main feeding area of most farm crops and, where no effort was made to replace the consumed plant food, that the loss in fertility occurred from the top downward. This has been found not to be true, says R. H. Bray, soil analyst of the U. of I. agronomy department.

In light of this new knowledge, explains Bray, it would be more practical and economical for farmers to begin replacing plant food either through manures or commercial fertilizers before the subsoil has been mined. To allow both the surface and subsoils to decline in fertility before treatment is started means that building up the productivity of the land will be slow, since it takes a longer time to increase the fertility of the subsoil than the surface soil. Experiments show that after the first initial increase in productivity resulting from surface treatment, a gradual increase in productivity occurs which is accompanied by an improvement in subsoil fertility.

When a soil improvement program is being planned, tests should be made of the subsoil at 10 to 12 inches and at 20 inches deep as well as of the surface soil, it is said. This is especially important where it is likely that the soil is low in phosphorus and highly acid, for such subsoils should be given special attention in the treatment program.

## Farm Conservation Plans Under the New Law

Farmers in 11 counties are in the midst of rounding up 25,000 tons of corn fodder and stover as Illinois' part in the AAA farm conservation program for the relief of food shortages in western states. A total of a million tons of forage is being sought at this present time in Illinois, Indiana, Ohio, Minnesota and other adjacent states, including several foreign countries.

It is of great interest in seeing fodder and stover under the program now being carried out, especially by coming to in the farm adviser's office, it is to be noted that the plan is not a new one, but has been approved from Washington, but as soon as the law is passed, the government will give the order in which farmers sign the applications for contracts.

At present, a farmer will find that a ton of a half of corn stover, so that the total amount of the contract will be a ton of a half of about 17,000 tons of corn stover, including the food shortages of farmers in these counties. The government will pay for the first three parts, which will be the first three parts of the contract, for 1000 bushels of corn stover. The established price for the corn fodder and stover is \$7.00 a ton.

Farmers in 11 counties in Illinois are now entering to sell will not be bought outright by the AAA, but will be sold to the F. O. B. House, which is a division of the College of Agriculture, University of Illinois, who is in charge of the farm conservation program in Illinois. The government will pay for the first three parts of the contract, but the government will pay for the first three parts of the contract to sell fodder and stover will be brought together with buyers through a federal agency to be established in Kansas City, Mo.

In case contracts are not completed by April 1 of next year, the government will either buy the material or sell it at a factory settlement, provided the forage is of that grade No. 1 or better.

All corn fodder and stover will be contracted for at least one grade and established standard. Grade No. 1 of fodder or stover shall have all or nearly all of the leaves attached and shall be green or greenish yellow in color, sound and sweet, well cured and shall not contain more than a trace of foreign material. Grade No. 2 shall have the majority of the leaves attached, may be yellowish brown in color, shall be well cured and may include not to exceed 10 per cent foreign material. All grades of fodder or stover must be cut and cured in the stack before being hauled.

Prices to be established for the different grades are: No. 1 corn fodder—whole, \$8.00; tons shredded or threshed, \$7.00; No. 2 corn fodder—whole, \$7.50; shredded or threshed, \$6.50; No. 1 corn stover or wheat corn stover—whole, \$7.00; shredded or threshed, \$6.00; No. 2 corn stover or wheat corn stover—whole, \$6.50; shredded or threshed, \$5.50.

In case prices are F. O. B., the farmer's shipping point for hauled stover or fodder. The secretary of agriculture will appoint inspectors who will inspect the fodder or stover before it is loaded on the point of shipment.

### Illinois Farmers Sifting Outlook On Feed and Stock

Production of both grain and live stock threatens to get out of hand again within a few years, thereby leaving farmers in another cycle of ruinous, low prices unless producers plan accordingly.

This summary of the feed and livestock outlook, which is based on evidence collected by the Bureau of Agricultural Economics, U. S. Department of Agriculture, has just been presented to official county representatives in a series of nine regional meetings held by the extension service of the College of Agriculture, University of Illinois.

These regional conferences are the first step toward a series of state-wide community meetings at which every corn-hog farmer will have a chance to get the facts on the present economic situation and to cast his vote on the question of a state program for 1935. After the 1934 corn-hog contract terminates on November 30, there will be no control program in effect with respect to grain or livestock and no further plans are made.

Plans for the community meetings in the 12 counties of the north were started as soon as county farm advisers and members of the county corn-hog allotment committee returned from the regional meeting. Depending on the community meetings, a county meeting will be held in each county for all community representatives of the corn-hog control association so that they can consult with the meetings in their respective neighborhoods. These community meetings will be open to all corn-hog producers, whether or not they are participating in the present control program.

The economic situation that grain and livestock farmers will face in 1935 will be almost the opposite of conditions that existed at this time last year, it was pointed out in the regional meeting. Farm supplies have been cut into so heavily that they are now on the shortage side. Livestock supplies, too, may be cut very sharply, but the shortage in feed will be more serious than the feed shortage resulting factor than livestock prices.

This has put a premium on feed supplies. On the basis of past experience this threatens to stimulate an undue increase in corn acreage. This in turn would bring ruinously low feed prices and lead to an overproduction in live stock raising. Livestock prices would then collapse, and corn-hog producers might be right back in another of the disastrous cycles that would result with the present use of a judgment campaign.

The series of community meetings is being planned so as to get the results of the Illinois poll in Washington before October 15 when it will be considered along with the outcome of the vote in other states.

-4-

### Save Oats Now Feeding Will Bring Profit In Spring

Hard pressed as they are for seed to maintain their eight or nine million acres of livestock, Illinois farmers can hardly afford to continue sending out of good seed quality and adapted varieties, it is reported by J. C. Eckenman, chief in crop extension at the College of Agriculture, University of Illinois. Oats of this kind now threaten to be so scarce that it will command a premium as seed next spring, he said. One county, Champaign, is conserving its supply by cooking oats, as well as hays and soybeans, under a plan similar to that used for the corn loans. Loans on the cooked oats, soybeans and wheat will be advanced at the rate of 65 per cent of market quotation.

-4-

Repetition Of "Lean" 1934 Crop Season Is Unlikely

A repetition of the disastrous crop season of 1934 is not likely in the immediate future, and therein lies hope for the farmer who is planning ahead, in the opinion of Dr. L. J. Norton, of the agricultural economics department, College of Agriculture, University of Illinois.

For the farmer who is looking quite a ways ahead, the decreased numbers of hogs, cattle and sheep on account of the short feed supplies means that the balance between livestock and feed prices is likely to be more favorable to livestock after the 1935 crops are harvested than is the case at the present time, he said.

In view of this prospect, it will be profitable to maintain good foundation breeding herds wherever it is possible to do so in any way, even in areas where feed supplies are very short.

Reasonably favorable prices for feedstuffs and for fat livestock are in prospect for this fall and winter as a result of the short crops of feed grains and the prospect of short supplies of fat stock.

The balance will likely be in favor of feedstuffs, but they will not be so high in price or in relation to livestock prices as they would have been if production had not been so drastically curtailed.

"The 1934 crop of feed grains in the United States will yield about 56 pounds for every 100 pounds produced as the annual average from 1927 to 1931. The 1934 crop of hay will yield about 67 pounds for every 100 pounds raised in the 1927-1931 period.

"Although the Illinois corn crop is short, it is good in comparison with those in states where the midsummer heat and drought practically destroyed the crop. In Illinois, for example, the crop is estimated at 62 percent of the five-year average, while in the five states of South Dakota, Nebraska, Kansas, Oklahoma and Missouri, the crop is only 17 percent as large as the five-year average.

"In spite of the very short corn crop there is a better balance between hog numbers and feed supplies than would have been the case if there had been no AAA corn-hog adjustment program. The 1934 spring pig crop in the United States was estimated at about 70 per cent of the average of the past three years and the number of cows to farrow in the summer and fall of 1934 was forecast to be slightly above than 60 per cent of the average for 1931-1933.

"Usually curtailment in hog numbers follows short corn crops. The fact that hog numbers already have been greatly reduced will lessen the necessity for the drastic liquidation in hogs which usually occurs after short corn crops and will maintain a better balance between corn and hog prices during this winter than would have been possible if the control plan had not been in operation.

"Reports to the U. S. Department of Agriculture indicate that 30 per cent fewer cattle will be purchased for feeding this year than in 1933."

-4-

High Feed Prices Fix Doom Of Poor Types Of Animals

Mounting premiums on feed spell the doom of all the poorer animals among the eight or nine million head of livestock on Illinois farms, and getting rid of such stock is the first step in conserving short feed supplies.

This is the recommendation of members of the dairy and animal husbandry departments of the College of Agriculture, University of Illinois in a special leaflet which they have just prepared. It is designed to answer the many inquiries of farmers who are hard put to make their available feed maintain the livestock on their farms.

Feed not only will be too scarce but also too high priced to waste on low-producing or inferior animals, the leaflet points out. Not only low-producing dairy cows but also inferior animals of all kinds and ages should be disposed of as soon as possible, it was recommended.

Silage I. Prisel I. L. 19-19. Lamb Feeding Cost 22

Shred of show, and especially those who have plenty of silage available, will be the ones most likely to cash in on the favorable outlook for lambs during the coming winter, according to W. C. Howland, assistant chief in sheep husbandry at the College of Agriculture, University of Illinois.

Feed costs will be high and profits will be eaten up unless the lambs are fed to gain fast, he pointed out. "Good gains generally are cheap gains, as they mean a large amount of feed and a quick investment in the production of the lambs.

"Feed costs will be even more important than in the expense and returns of lamb feeding this season than was the case a year ago. For years, especially here, it cost at least twice as much to fatten a yearling ewe as it will not be so easy to get a yearling over the year."

"Silage is a relatively poor feed and may be used as the only source for fattening lambs, if it is properly supplemented to make up for the lack of protein and mineral. When lamb raising is not in addition to the silage, it is essential that a protein concentrate such as soybean oil meal, cottonseed meal or fish meal be included in the ration. Likewise, some simple mineral supplement should be given over the silage. About one-fourth ounce of the protein supplement daily for each lamb is usually enough.

"In a test last year at the U. of I. College of Agriculture, a mixture of equal parts of salt and finely ground limestone did on the silage at a daily rate of one pound for each 10 lambs, seemed to provide ample mineral for the 90-day period. The average daily ration in this case was about 1 1/2 bushels of corn, 1/2 bushel of soybean oil meal, 1/2 bushel of silage and 1/2 pound of salt and limestone.

"Recent rains which have interrupted fall plowing have added to the farmer's chances of making a profit. "Good is an inconsiderable feed of lambs can't be gotten in utilizing it efficiently."

-15-

Soybean Seed From Beans Infected By Blight Disease

Wilsons as the rains have been in a great way, continued dry weather this fall may play havoc with the grain crops of the State, but barrels of soybeans sold by Illinois farmers will have at this fall, in the opinion of Benjamin Koehler, crop pathologist of the College of Agriculture, University of Illinois.

Exceptional moisture in late summer and early fall is particularly favorable to the development of what is known as "red and stem" blight, and already reports have been received by Koehler indicating that the disease has broken out in soybean fields in several parts of the state.

The only practical remedy known at the present time, explains Koehler, is to use special care to get the beans harvested as far as possible when a seed is ripe. If there is considerable moisture in the stored beans, the disease fungus spreads readily and multiplies the disease.

Symptoms of the disease are usually overlooked in the vines, but the usual damage will be readily observed when the beans are finally examined next spring. In 1926, when a severe infection of "red and stem" blight occurred in Illinois, many of the seed lots grown that year from Illinois went open being tested at the U. of I. College of Agriculture. Consequently if the rainy weather that prevailed over a large part of the state in September should continue, the blight will undoubtedly cause considerable damage this year.

-16-

Drowth-Damaged Corn Not Likely To Beat Last Year's Stock

There is little danger of containing live stock for the fall and winter, says Dr. Robert Graham, chief in animal pathology and diseases.

Immense quantities of grain have been raised by the U. of I. pathology laboratory relative to the possible poisonous properties of growth corn, as well as sudan grass, and apparently near to the corn raised to feed either of the foregoing.

Of the many samples of suspicious growth corn that have been tested in the laboratory, to date not a single specimen has proved to be poisonous, Dr. Graham said, although it is known that certain plants could develop fatal diseases if hydrocyanic acid under arrested growth, the danger in the case of corn seems to be rather doubtful.

The poisonous properties of corn are also being recognized during certain stages of growth, but there has been little evidence of injury manifested to live stock was not obtained in any instance. An experimental horse was fed the corn under a trial of three years without showing any ill effects.

Illness which may be mistaken for food poisoning is sometimes caused by the sudden change in rations, Dr. Graham pointed out. This is particularly true in cases where the animals have been on short pasture and on in a rundown condition. Recent rains have improved the pastures and as a result cases of laminitis have been observed in horses that had nothing to eat but hay. This ailment, they are convinced, is an intestinal disturbance, the cause usually being a sudden change in diet or overfeeding animals in poor condition.

-11-

Home Fires Spread Heavy Damage Each Fall In Illinois

Nearly \$20,000,000 in property is destroyed and many lives are lost each year in the United States, with Illinois one of the heaviest losers, because people fail to examine their chimneys, flues and other heating equipment before starting fires in the fall, says Miss Gladys J. Ward, home management specialist at the College of Agriculture, University of Illinois.

Commenting on the national observance of Fire Prevention Week, October 7 to 13, Miss Ward points out that fire caused the death of 1,415 people in the United States in one year, almost 10 per cent of whom were residents of Illinois. In the past 10 years, approximately 4,000 people have burned to death in this state, a third of them being children under 10 years of age.

House fires which average nearly 1,000 daily in this country lay waste a property damage amounting to \$12,000,000 annually, while the total loss from all types of fires aggregated more than \$50,000,000 in 1934.

Before lighting home fires in the early fall is the time to inspect, or to inspect and clean out defective chimneys, flues and fireplaces, if this work was not done during the regular spring house cleaning, says Miss Ward. Much of the loss of life and property also could be prevented, if a fire extinguisher was a part of the equipment of every home. Kept within easy access for quick use and inspected and re-filled regularly, a hand extinguisher would quench a large majority of the common home fires before a great deal of damage was done. A well kept carbon dioxide extinguisher and a hand one are also excellent aids in putting out small fires. The latter, especially in the kitchen, will many of the fires caused by spontaneous combustion. The latter could be prevented by keeping oily clothing in tightly closed drawers, she said.

## Increase in "4" District Enrollment as Favorable Sign

That the things are looking up in agriculture here in the fact that the total enrollment for the year 1934-35 in the College of Agriculture, University of Illinois, is the largest since 1930, is reported by Dr. E. J. Edelson, Dean of the College. The total enrollment for the year 1934-35 is 1,100 students, an increase of 100 over the enrollment for the year 1933-34.

Dr. Edelson is confident that the increase in enrollment is a favorable sign for the future of agriculture in Illinois. He points out that the enrollment in the College of Agriculture is a barometer of the state's interest in agriculture. The other two divisions of the College, the College of Home Economics and the Extension Service, are also showing an increase in enrollment. This is due to the fact that more and more farmers are turning to the College for help in their farming operations.

The increase in the enrollment of the College of Agriculture this year is a gain of 100 over the enrollment for the year 1933-34. This is a 9.1 per cent gain in enrollment. The enrollment in the College of Home Economics is also showing an increase. The enrollment in the College of Home Economics this year is 1,100 students, an increase of 100 over the enrollment for the year 1933-34. This is a 9.1 per cent gain in enrollment. The enrollment in the Extension Service is also showing an increase. The enrollment in the Extension Service this year is 1,100 students, an increase of 100 over the enrollment for the year 1933-34. This is a 9.1 per cent gain in enrollment.

Not only the enrollment, but also the quality of the students is showing an increase. The students are more interested in agriculture and are more active in their studies. The junior class is the largest since 1930, and the senior class is also showing an increase. This is a sign that the students are more interested in their studies and are more active in their studies.

The increase in the enrollment of the College of Agriculture is a favorable sign for the future of agriculture in Illinois. The enrollment in the College of Agriculture is a barometer of the state's interest in agriculture. The other two divisions of the College, the College of Home Economics and the Extension Service, are also showing an increase in enrollment. This is due to the fact that more and more farmers are turning to the College for help in their farming operations.

The enrollment for the entire university, as of October 1, is 10,616 students, an increase of 678 over the previous year, or a gain of 6.62 per cent. About one-fourth of the gain in the entire university was recorded in the agricultural college.

-4-

## Feed Crops Being Extended To Take In Hay Crops

Seed shortages in the South-stricken areas are so critical that Illinois farmers are being urged to conserve their seed, as well as corn, fodder and hay, under the AAA forage conservation program. Announcement of this has just been made by J. C. Hackler, crops extension specialist of the College of Agriculture, University of Illinois.

The AAA corn, fodder and straw program to value a total of 155,000 tons in Illinois is still underway, but the seed situation in the state farther west has become so critical that a call has now gone out for hay, too. Regional inspectors pointed by the AAA, as well as county inspectors, have been asked to take inventories of all available supplies of all hay, red clover, soybean, vetch, lespedeza and all available types. In some areas where there is a shortage of hay, it may be necessary to request for hay from other areas. The hay shortage that might develop is more than the corn fodder and straw would bring.

Illinois Farmers Organize To Fight 1935 Chinch Bug

Corn growers in Illinois are already arming themselves in defense against a probable chinch bug attack in 1935, with farmers in southern Iroquois and Vermillion counties leading the way, according to W. F. Flint, chief entomologist of the Illinois State Natural History Survey and of the College of Agriculture, University of Illinois. Farmers in that section are campaigning to eliminate all small grains during the coming year.

At the present time the chinch bugs, which have destroyed millions of dollars worth of crops this year, are flying into winter quarters. Next spring, however, the pests will come out of hibernation and begin feeding on small grains, particularly wheat and barley. It is at this stage that a large group of corn growers in east-central Illinois expect to defeat the bugs, for there will be no small grains for them to feed on, if present plans are carried out.

Authorities at the U. of I. College of Agriculture do not recommend this particular method of combatting chinch bugs for the entire state, but the movement illustrated one way of fighting the destructive pests where farmers will organize in a concerted drive.

Early in September a group of farm leaders in the two counties met to consider what could be done to protect their 1935 corn crop from the chinch bugs. Sweet corn is an important cash crop in this area, and almost any method that will ensure a minimum of insect damage is justifiable. Representatives of the U. of I. College of Agriculture and the Natural History Survey were called in to suggest ways and means of combatting the pest.

As a result of this and subsequent meetings, special agreement forms were printed, township chairmen were elected to lead the movement and approximately 97 per cent of the farmers in the area are believed to have pledged themselves not to grow wheat, barley, rye, oats or other small grains in 1935. The acreage formerly devoted to these crops will be planted to clovers, soybeans and other legumes that are not eaten by the chinch bugs, as well as some additional sweet corn acreage. Furthermore, the corn will be planted later than usual. Thus, when the insects come out of winter quarters next spring there will be a minimum of their favorite foods on which the first brood of bugs normally develops.

Illinois Farmers Aided By 35-Year-Old Lining Tests

Illinois farmers who had reasonably good stands of alfalfa and sweet clover this summer, while non-leguminous hay and pasture crops were withered by the drought, reaped the benefits of 35 years of experiments in this state dealing with the value of limestone in crop production, it is revealed in a recent bulletin published by the College of Agriculture, University of Illinois.

Alfalfa and sweet clover, because of their deep-rooting characteristics will grow well in spite of prolonged dry weather, provided the soil is not in an acid condition. But in many fields the acidity of the soil must be neutralized by limestone before a good stand of legumes can be grown. Thus many farmers who have followed the lining tests conducted by the U. of I. College of Agriculture had hay and pasture this summer regardless of the drought.

It was back in 1901 that the first of hundreds of field tests dealing with soil acidity were begun, explains F. C. Bauer, chief in soil experiment station and author of the new bulletin entitled, "Response of Illinois Soils to Limestone." During the next 17 years more than 47 similar experiment fields were developed in different parts of the state, 31 of which are still in operation and have furnished facts relating to soil management problems.

Beef Cattle Conditions Near Pennsylvania Higher Markets

Conditions which will result in reduced supplies and calls for higher cattle prices are reviewed in a leaflet entitled "Cattle Situation" prepared by a special committee of staff members of the College of Agriculture, University of Illinois. First, there is the great decrease in the cattle population of the country as a combined result of the drought, heavy feed on hand and the federal cattle buying program, and second, there is the smaller number of cattle likely to be fed this winter on account of the reduced corn crop.

Numbers of cattle began to increase in the United States in 1926, but the number of cattle marketed did not increase until 1931. This follows the usual tendency for change in number of cattle marketed to lag behind an increase in numbers in breeding herds. This lag was lengthened out in this cycle by low prices for cattle which caused owners to hold their stock. Once the period of increased marketings sets in, it has usually run for several years, during which cattle prices, after a sharp period of readjustment, have tended to range about a fairly stable level.

The drought of this summer together with the cattle purchase program of the federal government has concentrated into a few months a reduction in numbers which would normally have required several years. Through September, about six million head had been purchased by the government. The latest reports indicate total purchases will be from 7<sup>1</sup>/<sub>2</sub> to 8 million head. Although part of this will be shipped to southern and western markets, the larger part either has or will be brought red for relief purposes. This will reduce cattle numbers in the country by very substantial amounts. A crisis of restriction is likely to follow. More favorable price levels for cattle may be expected after this liquidation is completed.

Information collected by the U. S. Department of Agriculture about August 1 indicated a decrease of 7 percent or more in cattle feedings this fall and winter compared with a year earlier. Since that date, however, shipments of stockers and feeders from the four principal sources have been unusually heavy, the total movement for the three months, August to September 1, being 20 percent more than that of a year ago but approximately the same as in 1931 and 1932. In all probability these shipments include a considerable number of cattle which have been bought principally to utilize fall pasture and coarse rations. Consequently these shipments will contribute much less to the total supply than marketed next spring and summer than their numbers might indicate. Following the sharp corn crops of 1931 and 1932, the supplies of finished stores coming onto the market the following years were greatly reduced in comparison to receipts of "carried over" and "short fed" cattle, creating a wide range between the prices of the higher and lower grades. Reports indicate that a larger quantity of yearlings and a smaller proportion of calves will be fed, no doubt, in response to shipments to clearance of grain fields.

A factor of uncertainty in the prospects for all farm products is the outlook for business and consumer incomes. A period of a revival in trade would reinforce the effect of current supplies on cattle prices. On the other hand, if there is little or no improvement in business conditions, the advance in price will be much less marked. In spite of the setbacks which have taken place in business activity in the last three months, the general trend in activity is probably upward.

Over a period of time changes in beef cattle and dairy cow prices show strikingly close fluctuations and higher beef cattle prices will tend to lag behind prices of dairy cows. Moreover, the increased slaughter of dairy cows and heifers in the first part of 1934 indicates that marketings were thirty percent larger than in the same period in 1933. These conditions could be higher prices for dairy cows.

### Roofs Get First Attention In FHA Repair Activities

Better roofs and fresh paint are the two most important of the \$22, 400, 000 worth of building on Illinois farms, and now with Federal Housing Administration funds becoming available is the time to take care of both of the roofs, says W. A. Foster, rural architecture specialist at the College of Agriculture, University of Illinois.

Replacing old worn-out roofs and before winter sets in will stop the damage to the buildings and its contents, will improve the appearance of the structure and add to its value, Foster reported last.

The new roofs should be selected on the basis of economy, fire resistance, appearance and weather resistance, as well as cost, points out Foster. It is false economy to buy a poor roof that requires maintenance in a few years, while a good one will need no attention for 10 years or longer.

If the roof is to be made of wood shingles, only those with heavy cutts and cut free from rot or grain rot should be used, he said. When a metal roof is preferred, the material selected should be that for which the best of quality is staged on each side. In the case of corrugating roofs, by weight 24-gauge with a mineral or terra-lit lining will usually have the greatest resistance. If composition slate is to be used for the roof, 12-inch-sized units, rather than large pieces should be selected. A little investigation will be helpful in choosing the roof best adapted to the particular building. It should, of course, be built according to the recommendations of the manufacturer.

Better roofs on the farm buildings of the state would stop more than one waste in rural life, he says, Foster recalled last.

The best roofs are made after a survey of the quantity and stored articles than it will be to cover the building. A kitchen sink was grain unfitted for sale or use. Do not forget that it is important to use a drainage and sealing to articles and of good. Materials should be used for woodwork, rats cut rafters, and a plaster roof should be only for a fabric.

### Illinois Sets New Records For Heavy Haul Through

Heavy haul records for this through the course of the year, judging from the way they came in the front in horse-drawn contests in the College of Agriculture, University of Illinois held throughout the state this summer and fall. More Illinois teams had good records than at any time in the past eight years, it is reported by D. D. Atkins, livestock extension specialist, who was in charge of the contests.

Although the state records established last year remained unbroken, three Illinois teams during the season just closed lifted 7, 000 pounds the full distance of 7 1/2 feet, or the equivalent of pulling six 1 1/2-inch plow furrows six inches deep in stubble ground. One of these teams was a 4, 000-pound pair owned by Charles Lett, of Sandwich; the second team, weighing 3, 000 pounds, was owned by Homer Bradford, of Pontiac, while the third team to pull the full distance was a pair weighing 2, 100 pounds owned by Gordon Weston, of Allerton. This team lifted 75 percent of its own weight. Few teams have ever pulled the record, it is said.

The all-time records were set in 1917 by two teams owned by Willard Phillips, of Springfield. In the light class a Rhode Island weight team of 1, 000 pounds pulled a lift of 1, 000 pounds, while in the heavy class a team of 1, 000 pounds pulled a lift of 1, 000 pounds.

Final Count of Illinois Ballot. Favors AAA Program

Almost 75% of Illinois farmers voting in the government's nation-wide AAA corn-hog referendum favored an adjustment program dealing with corn and hogs in 1935 by a count of 17,811 to 11,774 and approved the issue on a simplified, one-contract-per-farmer program dealing with grains and livestock to become effective in 1936 by a poll of 17,811 to 11,774.

These are practically the final results of the referendums so conducted throughout the state by officials of county corn-hog production control associations.

The sentiment among the 44,000 corn-hog signers who voted was three to one in favor of the first question of an adjustment program dealing with corn and hogs in 1935. A total of 17,811 voted favorably, while only 11,774 were opposed. Counting the votes of farmers who do not have 1934 corn-hog contracts, as well as of signers, the vote on this question was 17,811 favorable to 11,774 opposed.

Contract signers voted separately first to give in favor of the second question of a simplified, one-contract-per-farmer adjustment program dealing with grains and livestock to become effective in 1936. A total of 17,811 signers favored this question, while only 11,774 were opposed. In total vote, including both signers and non-signers, was favorably by a count of 17,811 to 11,774.

In not a single one of the 101 Illinois counties did the count of signers vote down the first question, while the second was defeated only in three counties on the basis of all contract signers' votes. The second question lost 177 to 131 in Boone county vote of AAA cooperators, 177 to 131 by Kane county cooperators and 131 to 177 in the Tuscarora county vote of signers.

Boone, Kane and Tuscarora counties lost the second question when the votes of contract and non-contract signers were added together. The margin was 177 to 131 in Boone county, 131 to 177 in Kane and 131 to 177 in Tuscarora.

Three other counties, Grundy, Hancock and Schuyler, voted down the second question when the ballots of non-signers were added to those of signers. The margin was 131 to 177 in Grundy county, 131 to 177 in Hancock and 131 to 177 in Schuyler. However, these three counties were in favor of the second question on the basis of the vote of AAA cooperators alone.

Even when the vote of non-signers was added to that of the signers, the first question was defeated only in one of the 101 Illinois counties and then by a narrow margin. That was in Grundy where the total count was 131 opposed to the first question compared to 177 in favor of it. Among the contract signers, alone, the first question carried even in Grundy county by a count of 177 to 131.

In staging the referendums, corn-hog production control associations held a total of 1,178 community meetings which were attended by a total of 75,000 farmers.

Before voting on the two questions, farmers heard an explanation of state loan information from the bureau of agricultural economics, U. S. Department of Agriculture, showing that the production loss of grains and livestock this year is estimated at \$100 million unless farmers plan accordingly. Action was held to be necessary at this time, because after the 1934 corn-hog contract terminated on November 30, there will be no adjustment program in effect either on feed grains or on livestock.

Good Seed Curing And Storage To Save Corn Income

Providing good curing and storage conditions for their seed corn this winter, rather than poor or even average conditions, will be worth \$1,000,000 on next year's Illinois corn crop, should 1935 be a normal year and corn prices remain at 50 cents a bushel.

This is revealed in eight years of records kept by central Illinois farmers enrolled in the farm management service conducted by the College of Agriculture, University of Illinois, in cooperation with county farm bureaus. In these records, involving the growing of approximately 7,000 acres of corn, the difference between good and poor seed corn curing and storage amounted to 20 bushels an acre in the resulting crop. Even on very poor curing and storage conditions out the resulting crop two bushels an acre below what it was from good curing and storage of the seed. Two bushels an acre on the average normal Illinois acre of 3 million acres, with corn worth 50 cents a bushel, would add it to more than \$10,000,000 in corn returns.

By good curing and storage it is said that the seed corn is dried rapidly and protected from freezing until the proper moisture has been removed, explains R. H. Reed, agricultural engineer at the U. of I. College of Agriculture. These conditions are not met where the corn is hung on the stalk in the driveway of the corncrib as is practiced in many Illinois farms.

Rapid drying of seed corn can be done with the use of artificial heat, unless the weather is unusually favorable. For small quantities, the ears can be hung in the kitchen, on a wall stove or over a fire, in the chimney, or over an open hot air register. Large quantities of seed corn may be dried in the corncrib, a large or other buildings where a fire can be kindled. Care, however, should be taken to see that none of the ears is exposed to a temperature above 100 degrees Fahrenheit.

Ventilation is also an important factor in obtaining high quality seed corn, points out Reed. Unless the air immediately around the ears is constantly changed, the stacks here become laden with moisture, the drying will be much slower and an ideal condition is established for the development of molds.

State Vegetable Growers Will Meet November 4 To

Protecting Illinois' \$4-million winter vegetable growing industry from "counterfeit" certified potato seed will be among the important problems to be considered at the fourth annual meeting of the Illinois Vegetable Growers' Association to be held at Rockford, November 4 to 6, according to J. A. Powers, vegetable extension specialist at the College of Agriculture, University of Illinois. The organization with its membership of more than 1,600 vegetable growers is expected to take a vigorous stand against the distribution of potato seed in bags bearing the word "certified" as an imitation of the official seal of genuine certification, it is said.

Nut Interest To Center In The Haven Show On Nov. 16

Other towns and cities may have their world's fair exhibitions and their world's series baseball games, but little New Haven, known as the center of the pecan growing industry of Illinois, will have a distinctive event of its own when the Tri-State Nut Show is held there November 16. Aimed to further the already extensive nut-growing industry of Gallatin county, the show was started three years ago by H. C. Neville, county farm adviser, cooperating with the extension service of the College of Agriculture, University of Illinois. He has just announced plans for the 1935 show, which is expected to draw patrons from southern Illinois, southwestern Indiana and southwestern Kentucky.

## How Old Is Your Farm? (Continued)

Only a few years ago we saw a great number of farmers who had recently been in the grip of depression, and who had seen a revival of farm prices change. Dr. J. F. Norton, of the Department of Agricultural Economics, College of Agriculture, University of Illinois, writes:

Fortunate it is that the farmer is in the present situation of affairs, and that he has not been in the grip of depression, and that he has not seen a revival of farm prices, although it is true that the farmer is in a very difficult position, and that he is not out.

It is true that the farmer is in a very difficult position, and that he is not out. It is true that the farmer is in a very difficult position, and that he is not out. It is true that the farmer is in a very difficult position, and that he is not out.

It is true that the farmer is in a very difficult position, and that he is not out. It is true that the farmer is in a very difficult position, and that he is not out. It is true that the farmer is in a very difficult position, and that he is not out.

It is true that the farmer is in a very difficult position, and that he is not out. It is true that the farmer is in a very difficult position, and that he is not out. It is true that the farmer is in a very difficult position, and that he is not out.

It is true that the farmer is in a very difficult position, and that he is not out. It is true that the farmer is in a very difficult position, and that he is not out. It is true that the farmer is in a very difficult position, and that he is not out.

It is true that the farmer is in a very difficult position, and that he is not out. It is true that the farmer is in a very difficult position, and that he is not out. It is true that the farmer is in a very difficult position, and that he is not out.

It is true that the farmer is in a very difficult position, and that he is not out. It is true that the farmer is in a very difficult position, and that he is not out. It is true that the farmer is in a very difficult position, and that he is not out.

Old Style Illinois Farm Storage High-Raised New Corn

Illinois is a Illinois corn which grows well and good enough to hold 100- cent corn the average will not provide 100% its storage this fall with any losses more than four times their for on hand, as the opinion of W. A. Foster, rural architectural engineer at the College of Agriculture, University of Illinois.

Threshing, better storage conditions, and more care taken by corn storage facilities did not seem to back in that the corn was shrunken. But together with a reason, and a very low price, many of the present difficulties materially to the 1914 corn crop returns. The fact is that the leading the state will find it a practical proposition to store corn in a high raised bin so that the new corn may be held in the best possible condition.

To furnish a good storage bin, a concrete foundation, a tight floor, strong iron rods, and a good roof, are the main factors. It may be built in any one of a number of different ways, but the most common style in Illinois is made from the following specifications: To be 10 ft high, to end in an whether a grain elevator or the other side of the bin is to be the unloading device on the top. The distance between the bins should be the amount of corn normally raised and stored on the farm. In this state double cribs with a covered driveway between them, and a concrete floor, also provide a better space for wagon and other farm machinery.

When any crib is built, it should be well covered for protection from rain. This fall, many farmers will be tempted to store their new corn in old, and it will be a mistake. Foster believes that the best way to store corn is in a high raised bin. If it is suggested that the old style corn cribs are still in use, and do not need crib storage, it may be more practical to build out the old cribs and store it in a bin so that the best crib space is available for the new corn.

-4-

Export Value of Illinois Farm Products For Next Season

Although Illinois farmers are now considering in their 1914 production plan will have to take into account that the total value of agricultural exports is still increasing, according to reports which the College of Agriculture, University of Illinois, has received from the Bureau of Agricultural Economics, U. S. Department of Agriculture.

In total value of agricultural exports from the United States in the year ending June 30, 1914, there was a 10% increase over the previous year. Although some important products showed a substantial increase. The value index of exports of 44 leading farm products in the past year stands at 114 as compared with 100 in 1913-1914, when the average period of 1913-1914 is used as a base average of 100. This index of the value of agricultural exports in 1913-1914 was the lowest since 1907-1908.

In spite of the decrease in the value of exports, the value of the export agricultural products shipped out of this country last year, exclusive of forest products, was greater than in 1913-1914, or \$7, 700, 000 in 1913-1914 as compared with \$8, 000, 000 a year before, the federal bureau states. This increase in the total value of the exports was brought about by the general rise in commodity prices.

Although the volume of exports of many farm products declined, there was an increase in the exports of several other products of which the United States regularly produces an exportable surplus. Notable among these are wheat, corn, pork, beans, oranges, prunes and certain other dried fruits.

### Choice of Beef Cuts for Family Budget

Stretching the family budget to include the best quality beef is not so difficult, in case of right prices, as it is. It is, however, by the cuts of beef that usually the greatest part of the family meat cost, says Lester Bull, meat specialist at the College of Agriculture, University of Illinois.

Porterhouse and sirloin steaks and rib roast, owing to their limited proportions, are always expensive. There are, however, many other cuts of beef at more moderate prices. In most cases these are just as nutritious as the more aristocratic steaks and roasts. Furthermore, when properly cooked, they are quite palatable.

Many families prefer corned beef roast, not only because it calls for about three-fourths as much as the rib roast, but because there is less waste, explains Bull. Rump fore and hind, brisket, and round, should be pot-roasted rather than roasted. For the same reasons, cheap ribs and chuck steaks are often bought by shrewd housewives instead of the better-known rib cuts. Round last round, cheap pieces should also be pot-roasted.

Round steak, which is usually priced at two-thirds the cost of porterhouse and about four-fifths that of sirloin, is a rather economical cut. If the steak is cut thin, it should be fried, but if cut in such a thickness that it should be prepared as a crisis of oil, thereby overcooking it, it loses its characteristic.

Tripe is as good as any other meat for stews, soups, and in making string beans. When properly fried and quite tender, it is a staple for this purpose and is economical as well as palatable.

Hamburger or ground beef is always a favorite with school children. If especially high quality hamburger is desired, the lower ribs and lung round steaks can have it ground, but more meat of equal quality can be had for the same money by having the butcher grind a piece of shoulder or round. The odd bits such as liver, heart and tongue are likewise less expensive than other ground beef pieces and at the same time lend variety to the diet.

An economical feature of meat, which is small, is the fact that it does not require the addition of butter, or other condiments to make it palatable. That is one of the most costly parts and so this small and economical cut is well adapted to the palatability of child's less developed taste.

-11-

### How Itself, Walk Record For Parents In Pullman

While parents may feel that their children are safest at home, for accidents to youngsters occur there, they equal in number, according to Miss G. M. Ward, home management specialist at the College of Agriculture, University of Illinois. Furthermore, accidents cause more deaths and disabilities on the United States between the ages of 7 and 14 years than any one of the dreaded diseases, she said.

There are three possibilities for lessening the serious hazards confronting children in the home, Miss Ward said. First, parents should give greater care and thought to home accidents, which are responsible for 60 per cent of the deaths of the youngsters before they are old enough to be sent to the streets for work, army service, sea-faring, or other hazardous occupations. It is better to explain how and when dangerous articles should be handled rather than allow the child to learn untaught experimentation. Third, parents lay a value on habits in their children by setting a proper example.

## Illinois Corn In Strange Position To Retain Honors

Although the average yield of corn in Illinois this year is better than for many other sections and consequently corn growers of this state have one of the best chances that they have ever had to win national and international honors, according to H. C. Hackleman, crop extension specialist at the College of Agriculture, University of Illinois.

During the summer and Great South West International Livestock Exposition, which is now in progress at Chicago, the corn must be in Chicago by November 15.

The state will want to improve on its feat of last year when it took the "crowning" crown of the world in a 100-bushel sample of yellow utility type shown by C. Ward Holmes, of Joplin, Missouri, Hackleman said. It was the first time in the world's history of the fair and grain show that the utility type had won the prize title, although it has had, in the past, many years that such corn has been the best in the world class. It is now at the show. Development of utility type corn has been a great success for the College of Agriculture and the state, and has produced higher quality grain.

This year, although the yield of corn is the shortest in more than half a century, it is of fairly good quality, especially in some sections of the state, Hackleman reported. In the state of Nebraska, Missouri and some of the states in the west which have a higher yield than Illinois from the drought will be hard pressed to put up the best strong competition at this year's hay and grain show, it was predicted.

Illinois' strength in the world's best corn crop will come from northern Iowa and northern Ohio. Growers in the latter state, especially, are out after Illinois' lead in the world's best corn crop and are after the grand championship of the show.

The region around Warren county, where Holmes, the present "corn king" of the world lives, is one of the best which has a good crop of promising quality this year, Hackleman reported. Other counties in that area with corn crops of fair quality are Warren, Knox, Henry, Whiteside and the eastern part of Henderson county and western DeWitt county.

Some strong samples also are expected to come out of an irregular shaped area in central Illinois including parts of McLean, Macon, Menard, Logan, Tazewell, DeWitt, Woodford and Linn counties.

The whole of southern Illinois has a crop of fair to fine quality corn, Hackleman reported.

Whether Illinois corn growers plan to enter the hay and grain show or not, it will pay them to save all the seed they can this fall, in the opinion of Hackleman. With the likelihood that good corn from the 1934 crop will be in heavy demand next spring, farmers will have a profitable outlet for all the good corn they can save this fall, he pointed out. Some farmers, when their corn is going into the crib, plan to pick out all ears that could possibly be used for seed and store them in a separate section of the crib.

General Principles of Soil Conservation

Soil is a limited resource and should be conserved for the benefit of future generations. It is the foundation of our food supply and the source of many of our raw materials. Therefore, it is essential that we take steps to prevent soil erosion and degradation. This can be done by planting cover crops, using contour plowing, and building terraces on sloping land.

Soil erosion is a natural process, but it can be accelerated by human activities. The removal of vegetation, such as trees and shrubs, leaves the soil exposed to the elements. Wind and water can then carry away the topsoil, leaving behind a layer of infertile subsoil. This process can be slowed down by planting trees and shrubs, and by using other soil conservation techniques.

Contour plowing is a technique that involves plowing and planting in rows that follow the natural curves of the land. This helps to reduce the amount of soil that is washed away by rain. Another technique is strip cropping, which involves planting rows of crops in alternating strips. This helps to break up the soil and reduce erosion.

Soil conservation is not only important for agriculture, but it is also important for the environment. It helps to prevent soil erosion, which can lead to the loss of fertile topsoil and the degradation of water quality. It also helps to reduce the amount of sediment that is carried into rivers and streams.

Soil conservation is a long-term investment. It takes time to plant trees and shrubs, and it takes time for the soil to recover from erosion. However, the benefits of soil conservation are long-lasting. It helps to ensure that we have a healthy and productive soil for many years to come. It also helps to protect the environment and the quality of our water supply.

Drilling is a common method of soil conservation. It involves drilling holes into the soil and filling them with a mixture of soil and fertilizer. This helps to improve the soil's structure and fertility. It also helps to reduce the amount of soil that is washed away by rain. Drilling is a simple and effective method of soil conservation that can be used on a variety of soil types.

Fertilization is another important method of soil conservation. It involves adding nutrients to the soil to improve its fertility. This helps to ensure that the soil has enough nutrients to support the growth of crops. Fertilization is a key component of soil conservation and is essential for maintaining a healthy and productive soil.

Soil Conservation in the United States

The United States has a long history of soil conservation. In the early 20th century, soil erosion was a major problem in many parts of the country. This led to the passage of the Soil Conservation Act in 1935, which established the Soil Conservation Service. The Service has since been instrumental in developing and implementing soil conservation programs across the country.

Soil conservation is now a widely recognized and practiced method of land management. It is used by farmers, ranchers, and homeowners alike to protect their soil and improve their land's productivity. The Soil Conservation Service continues to provide technical assistance and resources to help people implement soil conservation practices.

In the state of Illinois, soil conservation is a priority. The Illinois Department of Agriculture has established a Soil Conservation Division to coordinate and promote soil conservation efforts. This division provides technical assistance and resources to farmers and ranchers. It also works to educate the public about the importance of soil conservation.

The Soil Conservation Service has a number of offices in Illinois, including offices in Chicago, Springfield, and Peoria. These offices provide technical assistance and resources to farmers and ranchers. They also work to coordinate soil conservation efforts across the state.

New Varieties Of Apples Ready For Illinois Growers

Something new in apples will be offered to growers in a few months as a result of new varieties which are available to Illinois commercial fruit growers for planting between now and spring, according to L. L. McKim, associate pomologist of the College of Agriculture, University of Illinois. One or two of these new varieties undoubtedly will be put out by growers and are replacing trees that died during the summer or will be put out next planting time, he said.

Nurserymen and experiment station plant breeders have made noteworthy progress in the last few years, not only in developing new varieties, but in selecting bud sports from some of the older and more common varieties of apples. These new propagations are being tested by the experiment station of the College of Agriculture and by other investigators and can now be offered to growers with reasonable assurance of satisfaction.

Development of the new varieties marks another step in improving the quality and increasing the marketable and total state apple crop, which brought farmers an average cash income of \$1,377,000 during the three years 1931-1933, McKim said.

Of these new varieties, many are of or are sports of some well-known standard varieties as Delicious, Stayman, Jonathan, McIntosh, Rome and Pippin. Most of them produce fruit of a much deeper red color than the varieties from which they originated, and the color develops on the apple much earlier than in the case of the standard varieties. These new characteristics are a distinct advantage to the commercial grower, because he can harvest the crop somewhat earlier and get a market that will color up to U. S. No. 1 standard.

All of these varieties are well adapted to the regions in which the present varieties can be grown successfully, and, at McKim's, and are easily adapted in a small way either for commercial or home plantings.

Several new apple varieties that are of bud sports are also available to growers. A few of these include Early McIntosh, Tingo, Lady Howland, Orleans, Molok and Red Bird. For the most part these new varieties originated in the northern part of the United States, are adapted to a considerably cold winters and can be expected to produce good crops in Illinois.

-4-

Poultry Outlook Encourages Use Of Superior Rations

With the seasonal increase in egg prices and the encouraging outlook for the egg market this fall and winter, renewed interest is being taken in laying rations by Illinois poultrymen, whose flocks normally produce some two billion eggs annually, according to H. E. Alp, poultry extension specialist at the College of Agriculture, University of Illinois.

There are, of course, several good laying rations, but the best one given good results at the U. of I. College of Agriculture consists of both mash and grain mixtures. The mash is usually made up in 500-pound lots by mixing together 155 pounds of ground yellow corn, 100 pounds of wheat middlings, 65 pounds of meat meal, 100 pounds of wheat bran, 20 pounds of dried milk, 25 pounds of soybean oil meal, 40 pounds of alfalfa leaf meal and 5 pounds of salt. For winter feeding one pint of cod-liver oil is added to each 100 pounds of mash. This is kept before the birds in feed hoppers at all times.

The grain mixture, when made up in 100-pound batches, consists of 40 pounds of corn, 30 pounds of wheat and 30 pounds of oats. This is hand fed, the birds being given 12 to 14 pounds for each 100 birds twice daily. Oyster shells, grit and any succulent green feed that may be available are given the birds freely.

## Refrigeration and the Winter Storage of Fruit and Vegetables

With the advent of the winter season, the question of how to store surplus crops becomes a problem. In this connection, the International Horticultural Congress, which met at the University of Illinois, has been a most interesting forum. It has been held this year, under the leadership of Dr. H. H. Henshaw, Director of the College of Agriculture, Urbana, Illinois. The first day of the Congress was devoted to the presentation of papers by Dr. H. H. Henshaw, Dr. J. H. Henshaw, and Dr. J. H. Henshaw, and the second day to the presentation of papers by Dr. J. H. Henshaw, Dr. J. H. Henshaw, and Dr. J. H. Henshaw.

The first paper presented was by Dr. J. H. Henshaw, of Chicago, Ill., on the subject of "Refrigeration of Fruit and Vegetables." He discussed the various methods of refrigeration, including the use of ice, cold storage, and mechanical refrigeration. He also discussed the various methods of storing fruit and vegetables, including the use of cellars, root cellars, and cold storage.

Although the use of mechanical refrigeration is increasing rapidly in some large cities, it is not so common in rural areas. In fact, in many rural areas, the only method of refrigeration available is the use of ice. This is a very expensive method, and it is not always available. Therefore, it is important to know the various methods of storing fruit and vegetables, and to know the various methods of refrigeration available in rural areas.

The use of mechanical refrigeration is increasing rapidly in some large cities, but it is not so common in rural areas. In fact, in many rural areas, the only method of refrigeration available is the use of ice. This is a very expensive method, and it is not always available. Therefore, it is important to know the various methods of storing fruit and vegetables, and to know the various methods of refrigeration available in rural areas.

Some of the methods of storing fruit and vegetables are: (1) the use of cellars, (2) the use of root cellars, (3) the use of cold storage, (4) the use of mechanical refrigeration, (5) the use of ice, (6) the use of dry ice, (7) the use of salt, (8) the use of sugar, (9) the use of oil, (10) the use of wax, (11) the use of paper, (12) the use of cloth, (13) the use of straw, (14) the use of sawdust, (15) the use of wood shavings, (16) the use of horse manure, (17) the use of cow manure, (18) the use of pig manure, (19) the use of chicken manure, (20) the use of guano, (21) the use of fish manure, (22) the use of bone manure, (23) the use of blood manure, (24) the use of hair manure, (25) the use of horn manure, (26) the use of hoof manure, (27) the use of horn manure, (28) the use of horn manure, (29) the use of horn manure, (30) the use of horn manure.

How to Handle the Horse in the Farm Household

Horses are being raised in Illinois in a way that is a source of economical trouble. It will be pointed out in this article, it is pointed out by W. L. Sauer, farm management specialist at the College of Agriculture, University of Illinois.

Next to man labor, the cost of the horse and mules is one of the largest items of expense on any farm in this state. This is not realized because horses are usually fed on farm grown grain and hay, and the extra outfit is necessary for their feed.

How widely the north and south differ in horse raising depending upon their management is shown in a study of horse raising in DeWitt, Illinois, and Piatt county farmers in cooperation with the farm management division of the U. of I., College of Agriculture. The net value of raising a horse here for the year varied from \$4.37 to \$76.41, or an average of \$30.51.

The number of hours of work performed by the horse ranged from 110 to 1,444 hours each, the average being 714 hours. The cost of a full year of horse labor averaged 6.4 cents. This varied from 2.4 cents on the low end to 12.2 cents on the high end, with the highest horse labor cost being on the farm with the highest horse labor cost. The cost of horse labor was closely correlated with the number of hours worked by each horse, although the total cost of keeping a horse varied widely and for many reasons. The average number of hours worked by a horse varied widely, and for many reasons. The average number of hours worked by a horse varied widely, and for many reasons.

Feed accounted for 30 per cent of the cost of the horse, labor for another 14 per cent, shelter 10 per cent, interest on investment 7 per cent, depreciation 6 per cent, and other 14 per cent. The cost of the horse varied widely, and for many reasons.

From these figures it is evident that the cost of horse power on farms can be reduced by cutting down the expenses of the horse and by increasing the amount of productive work done by each horse. The feed cost is the largest and the labor cost is the next largest. The cost of the horse varied widely, and for many reasons. The cost of the horse varied widely, and for many reasons.

The amount of work done by each horse can be increased by increasing the number of horses on a farm, by increasing the amount of work done by each horse, by planning field and other work in advance, by using the horses during the best periods for such work as plowing, by using the best hitches, by having fields properly arranged and by keeping the horses in good physical condition so that they are able to stand up under heavy loads when necessary.

How Insulation and Repair Cut Down Heating Bills

For every one dollar per cent of the average annual bill for heat of the 1,445,177 homes of Illinois could be eliminated this winter by using FHA plans to insulate and repair minor repairs about the house, as is outlined by W. L. Foster, rural architecture specialist at the College of Agriculture, University of Illinois. The saving in fuel alone would go a long way in paying off the government loan.

Next to removing and repairing roofs, the most important thing for dwellings and other houses in this country is to build out the walls and ceilings. Poor, loose construction and uninsulated walls and roofs are extremely wasteful. Often weather-stripping a door or window will save a large amount of money. The replacement of a broken glass in a sash or new panes will also provide needed savings.

No Winter Is Kind To Small Fruits Left Unprotected

Nobody would want an early winter if it is going to be, but the best thing for Illinois small fruit growers to do is to get their plants well covered before the first hard freeze comes, according to J. J. Kelly, chief of small fruits at the College of Agriculture, University of Illinois. The state has been producing 15 million dollars worth of small fruits during the past several years, but the crop next year and the years after that will be much smaller unless the protection of the winter, he said.

"Mulching is the best method of winter protection. The growth of the covering should be abnormally early. Enough leaves should be left on the necessary moisture is conserved for the plants. Then too, the fruits are kept dry longer than they otherwise would be.

"It is especially important that strawberries be covered after the plants have become dormant and before the first hard freeze. If the temperature is lower than 10 degrees above zero some covering by means of straw, sawdust or manure. The thin stand of plants in the early fall is the most vulnerable and should be covered to injury. Raspberries, blackberries and currants should be covered with a mulch which applied late in the fall.

"Straw, wild or tame hay, leaves, shredded manure, or a mixture of any of these may all be used as winter covering. The covering should be applied with care, as they pack. Mulches should be applied from around weeds and as possible, as they will foul the soil next spring. Chitin is a material which if it has been left exposed for several months will rot and cause all seeds in it to be germinated.

"For strawberries the mulch material should be spread about two inches thick over the patch. Next the rows should be mulched in the rows, leaving the middle to be cultivated during the growing season.

"Some growers have tried covering the space between the strawberry rows in the fall and allowed the weeds to be killed by frost. This is not recommended because the weeds usually grow through the mulch, the mulch is not uniform and it rots during the winter, making conditions less satisfactory for picking the following season."

Money Spent For Poultry Leucosis Cases Only Needed

Buying so-called remedies to rid your flock of leucosis disease, which includes such ailments as runny crop, big liver disease, white eye, neuritis and leucemia, is likely to prove a waste of money for Illinois poultrymen, in the opinion of Dr. Frank Thery, Jr., associate in animal pathology at the College of Agriculture, University of Illinois. As yet there is no known cure for the disease.

Although comparatively new in this state, leucosis is currently spreading throughout many flocks and threatens to become a serious poultry problem, points out Dr. Thery. It affects both sexes and usually occurs between the ages of 3 and 12 months.

In spite of the fact that birds contracting leucosis can not be cured, research investigations indicate that the disease can be controlled if poultrymen will carry out five more or less preventive measures, it is said. These include rigid culling to detect leucosis in the early stages of the disease, disposing of all diseased birds by killing and burning, buying hatchery eggs, new breeding stock or baby chicks only from disease-free flocks and stockholders and observing the most sanitary practices. The ill poultryman believes that his flock is infected with leucosis, immediate diagnosis can be made by a local veterinarian.

## Popular Simplifications Made In 1935 Corn-Hog Plan

Lifting of the restrictions on all other crops except corn and the dropping of the "contracted acres" will be the most popular changes with Illinois farmers of all those that have been made in the new 1935 corn-hog contract announced Monday, November 19, by the AAA in Washington, in the opinion of officials at the College of Agriculture, University of Illinois.

The new contract also permits that farmers adjust their corn and hog production only 10 per cent below the average of the 1932-33 base years instead of 20 per cent in corn and 10 per cent in hogs, as was the requirement in the 1934 contract. In the case of corn, farmers may adjust anywhere from 1 to 30 per cent below the two-year base average and receive farm credit payments in proportion.

If Illinois farmers participate in the new program about like they did in the 1934 plan, it will mean that they will get between 19 and 21 million dollars in benefit payments as a further addition toward having their purchasing power restored, officials of the agricultural college estimated.

At least four representatives from Illinois who were connected with the administration of the 1934 corn-hog program also contributed in an official way to the mass of recommendations upon which the new 1935 contract is based. They are J. R. Fulkerson, J. Rayville, a member of the state corn-hog committee; J. S. Bumgarner, McNabb, president of the Marshall-Putnam County Corn-Hog Production Control Association; L. A. Eckert, Mascoutah, a member of the state committee, and P. E. Johnston, of the farm management department, of the College of Agriculture and a member of the state board of review. All four were called to Washington when the 1935 program was being worked out.

Dropping of the "contracted acres," one of the most bothersome features of the 1934 contract, means that acre land withheld from corn production can be used for growing any other crop for any purpose, officials of the college explained. Furthermore, there is no limitation on the total acres devoted to cultivated crops nor on the total acreage of any particular crop, excepting corn.

The "contracted acres" feature was omitted from the 1935 contract partly to simplify compliance and partly to permit the greater flexibility in farming operations that will be essential in 1935 on account of the shortage of farm seeds and because of the destruction of many hay and pasture stands by the drouth.

Funds for the benefit payments under the 1935 contract will be raised by means of a processing tax beginning November 5, 1935, and continuing through one marketing year at approximately the current rate of \$2.25 a hundredweight on hogs and 5 cents a bushel on corn. The 1933-34 emergency programs and the 1934 production adjustment program require the collection of processing taxes through two marketing years, ending November 4, 1935.

Dean H. W. Mumford, of the College of Agriculture, University of Illinois; J. C. Spitzer, state leader of farm advisers, and F. J. Keilholz, extension editor, will be Illinois' official delegates to a regional conference to be held in Indianapolis soon after Thanksgiving, at which time the new contract and administrative rulings will be presented. Immediately following this conference, the program will be launched throughout the state, through county corn-hog production control associations.

### Featuring Horses In Stalk Fields Will Be Dangerous

Heavy death losses among horses and mules in the farmer who tried to save feed this winter by turning work stock out on cornstalk fields, according to a warning by Dr. Robert Graham, chief in animal pathology and hygiene at the College of Agriculture, University of Illinois.

It is true that feed supplies are the shortest on record. Unfortunately, however, it will be especially dangerous this year to try to get horses and mules through the winter by pasturing them on stalk fields. Some of the worst corn-ear-worm damage that the state has ever had, coupled with heavy rains, has caused much rotting and molding of the ears.

Already reports are reaching the U. of I. animal pathology laboratory of the widespread occurrence of a disease resembling the old-fashioned cornstalk disease so prevalent about 15 years ago. The malady, however, is not caused by eating the cornstalks but by consuming low-quality corn. Cattle also seem to be susceptible to the disease, although not so much so as horses and mules. Even horses pulling husking wagons have been known to develop the malady, points out Dr. Graham. Thus, Illinois farmers might well play safe by using hay to keep on the horses while they are being used in cornfields this fall.

If cornstalks are used for feed, as they must be on many farms this year, hogs and cattle can be pastured in stalk fields with less danger than any other farm animals, it is said. Even then, the stalks should be removed only a part of each day and thoroughly inspected each night for possible symptoms of the disease. When feeding this year's low-quality corn, farmers should inspect all of the ears for horses, mules and cattle.

The first symptoms of the disease are likely to be inappetence, sluggishness, or sleeping on the part of the horse, although the symptoms are not easily detected without careful observation. When these mild symptoms appear, however, a veterinarian should be called immediately, for only by prompt treatment in the early stages of the disease can the effect on animals be saved. As the disease develops, the horse begins to walk in circles, stagger and press against its mane or fence. These symptoms indicate a brain disturbance that is much easier to prevent than to cure.

This disease should not be confused with hydrocyanic acid poisoning which some farmers feared might develop from feeding dry-ear-damaged cornstalks this fall, or from feeding frosted millet, sorghum or sudan grass.

-M-

### Rockford Host To State Vegetable Growers' Meeting

Although Illinois is usually considered as a corn-hog producing state, the annual meeting of the Illinois Vegetable Growers' Association to be held at Rockford November 20 to 22, will be one of the outstanding farm conventions of the fall season, says L. A. Myers, vegetable extension specialist at the College of Agriculture, University of Illinois.

Out-of-state speakers will include J. G. Milnerd, who is in charge of soil potato certification work at the University of Wisconsin; I. C. Hoffman, widely recognized authority on greenhouse vegetable production from the Ohio State University experiment station at Wooster; Walter A. Marion, of Columbus, Ohio, past president of the Vegetable Growers' Association of America; and Garm Drown, of Detroit, Mich., one of the leading plant geneticists of the United States.

-M-

### Too Heavy Cut In Dairy Rations Lowers Herd Profits

Feed prices may be advancing faster than the market value of milk and butterfat, but Illinois dairymen who attempt to reduce expenses by skimping too much on the grain fed their 1,111,000 cows may find that they have also lowered their profits, says C. S. Rhode, chief in dairy husbandry extension at the College of Agriculture, University of Illinois.

Some revision in the amount of grain fed should be made on a number of farms to meet changing price ratios, but where the economy is carried to excess the results are likely to prove disappointing, it is said.

This has been revealed in experiments conducted at the U. of I. College of Agriculture in which three groups of cows were fed different rations for a year. One group received only alfalfa hay and silage. Another group was fed hay and silage plus one pound of grain for each 4.7 pounds of milk produced. The third group was fed rather heavily on grain, receiving one pound for each 2.2 pounds of milk produced, but was given only a limited amount of hay and silage.

At the end of the year, it was found that the cows getting only roughage produced an average of 27.3 pounds of milk daily, those on limited grain feed gave 28.4 pounds of milk and the cows getting heavy grain ration returned 29.2 pounds.

When the value of the milk, rather than the cost of feed, was considered, the cows receiving a limited grain ration earned the most profit above feed cost, those fed only roughage earned second in profit decrease, and the group getting the heavy grain combination netted the least profit over the cost of feed.

When the value of the milk was raised the order of profitability of the three groups was changed to what. When the milk was figured at \$1.50 a hundredweight, the limited grain cows continued to return the most profit, or \$48.31 each above the cost of feed. The heavy grain group earned second a profit over feed expense of \$45.79, while those fed only roughage earned last, a profit of \$41.75 in excess of the cost of feed.

The grain was figured at \$30 a ton, hay at \$60 and silage at \$5. Thus the average cost of feed for the roughage cows amounted to \$21.61 each, the limited grain animals \$16.11 and the group receiving liberal amounts of grain \$115.14 each.

-M-

### Illinois Growers Finishing Up 1930 Quality Turkey

Illinois breeders will not have to depend entirely upon Texas-bred turkey to grace their Thanksgiving Day dinners this fall, for Illinois growers are now finishing off some 2,500,000 fowls which they have been raising in confinement to produce exceptionally high quality meat, says H. H. Alb, poultry extension specialist at the College of Agriculture, University of Illinois.

Illinois has been producing about 11,000 turkeys annually, according to the most recent census, but most of the turkeys sold to Illinois consumers have been shipped into the state from western range areas. During the past year, however, Illinois turkey growers have been cooperating with the U. of I. poultry extension service in an effort to produce birds of superior quality to those brought into the state. Furthermore, they have organized themselves into a state association to educate Illinois consumers on the better quality of turkeys grown in this state. As a result of these efforts, fully 25 per cent of the turkeys produced in Illinois in 1930 have been raised in confinement and under the best of conditions. Growers' selection to be sure that their Thanksgiving Day meat will be top grade and well finished should look for an Illinois-grown turkey when making their purchases, says Alb.

Legislation for Pig Cholera in Pigs and Swine

Forty-two per cent of the cost of the vaccine used to protect pigs from the ravages of cholera can be saved. If in the future, all the live pig pigs vaccine had an early, and rubber in waiting until after the outbreak, says Dr. Robert Graham, chief in charge of pathology and bacteriology at the College of Agriculture, University of Illinois.

Immigration of hogs from cholera-infected areas is recognized as good insurance, but producers generally will not do so until the pigs weighed 45 to 50 pounds or more before having them vaccinated. It is suggested, however, is required than if the pigs are vaccinated at a younger age, and consequently the expense is greater. Likewise, more liberal vaccination is desirable with all hogs.

To eliminate the possibility of infection of the animals about 15 cubic centimeters of anti-cholera serum should be administered to each pig for each pig, explains Dr. Graham. With the serum being 50-100 cent and the time for a cubic centimeter, the total cost of the vaccine will be about \$1.00. This is a saving of \$5.00 per acre, and the cost of treating the pigs after the had become infected.

That early vaccination is possible because has been demonstrated in scientific tests conducted in the laboratory of the University of Illinois and in the field. One reason for the success of the University of Illinois College of Agriculture, 1,000 pigs between the ages of one and three were vaccinated with potent anti-cholera serum and virus. These pigs were kept in a stable and all the pigs were exposed to cholera either by the presence of the virus in the air or by injection of virus.

Some of the pigs contracted cholera during the period and it is believed to be susceptible to cholera, but the results of the experiment indicate that the disease at the time of vaccination had no influence on the length of incubation. Instead, it is believed that the susceptibility to cholera on such young pigs may have been affected by the presence of acute respiratory infections, intestinal parasites and pig typhoid, which break down the defenses of the pigs. With the proper care and attention, service to diagnose such diseases and the means of controlling them, says Dr. Graham, at the proper time, the disease can be eliminated and the loss of the pig, as Dr. Graham believes.

Mice Moving In: Old Insecticides Will Kill Them

This is a good time for mice. They are now coming back into houses, barns and other buildings to collect their share of the \$100,000,000 of mice which mice eat and must usually, in this country, are killed by G. L. Odell, a rodent specialist of the U. S. Biological Service. For the time being, however, it is now to wait for some new means of exterminating them, as Dr. Odell said. The old reliable method of using traps and poisoned bait will do.

If us 3 in a thorough way, a mouse can be exterminated. The following furnish two of the best means of destroying them. One is the use of a bait, consisting with the Dept. of Natural History Survey and the College of Agriculture, University of Illinois, in the control of rodent infestations of the Mississippi. The bait can be used safely, on a night, and can be prepared by mixing one part of the bait with one quart of dry cracked corn. This mixture should be placed at intervals along walls and in all places where mice are likely to find that will give effective control. Caution should be observed, however, for the bait is equally poisonous to children or other pets.

Terraced and Hot School Lunches

Whatever else we are able to conserve soil resources, we shall lose millions acres of rolling land used for the production of cultivated crops in Illinois will fail unless terracing is made the habit, according to Ralph S. H., agricultural engineer at the College of Agriculture, University of Illinois.

This fact, which figures in the present work of experiment for soil conservation, has never been demonstrated so strikingly than on the farm of Theodor Reuss, Bellville, St. Clair county, Ill., said.

Terraced cropland, laid out in a way which built up a slope and increased for the successful start of a field, is a better investment, Reuss said, it was pointed out. The reason, the farmer explained, was excessive erosion, fertilizer and seed washed away by the fall rains before corn or wheat started. If a terraced field is immediately planted in wheat, the soil can be well settled and established so that the soil holds the soil from serious erosion when corn and small grains are later planted.

Nine years ago Reuss on a hillside, a field in a tract of fertility as a result of sheet erosion. It was a good field, but a few years ago, during the land with farm machinery was ill-fitted. When, the soil had been washed down the slope when after a few years the soil had been washed down the slope.

Acting upon the suggestion of Dr. H. I. expansion agricultural engineer, Reuss built five terraces across this field in 1907 to grow a soil machine, seeded it to alfalfa and secured a good crop. Now this field is a good field, and wheat, the yield from the field was three times as much as before terracing.

In the beginning, this St. Clair county farmer had some trouble with his terraces, but he now considers them well laid out all the extent a piece in a construction and maintenance. At the end of the year, a large stone or gravel terrace had to be rebuilt with a slip barrier. But the erosion of soil is so that the entire field may be farmed as one unit. There are some small slides in the outlet ditch, but properly built brush dams on each side of the ditches, by excluding this field on the contour and by back-flooding to the ridges each time he plows, Reuss now has no difficulty in maintaining the terraces in good condition.

Hot School Lunches

Illinois' 1947, a rural school where a school lunch would be a better lunch this winter, if all of the school boys and girls could not dish with their noon-day lunches, in the opinion of Dr. Glenn A. Halpern, foods specialist at the College of Agriculture, University of Illinois.

Only a few schools in the state serve hot lunches in spite of all that has been done all over for this practice, she reported. In recent years some rural teachers and parents in various parts of the state have been cooperating with the U. of I. home economics department in developing a plan providing hot school lunches with the minimum amount of time, work and expense.

Studies made in these schools showed that the hot lunches really were the teacher, the parents and the pupils in a school for the a full amount of work was required. Fewer colic, improved work and better dispositions in the work, back evils and teachers have been noted. Teachers also report a better attitude, increased interest in school activities and a more enthusiastic response. The hot lunches have also offered a practical means for teaching about the value of nutrition and food habits, especially when the children are made full of the practicality of food preparation and service.

## Investment Made in L. Still Pays This Farmer

Four years ago, just when other investments were shaky, Carl Bormet, a Cook county farmer, put some money into an investment which he says has turned out to be the best one that he has ever made.

He invested in limestone and rock phosphate, just as hundreds of other farmers have done who have followed the teachings of the College of Agriculture, University of Illinois on the testing of soils, the spreading of limestone and phosphate and the growing of more legumes.

This year in a five acre field, the 11-acre farm produced plenty of home-grown feed for his 40 head of dairy cows. Twenty-five acres that were limed four years ago produced about two and a half loads of alfalfa hay to the acre for two cuttings this year, which will be enough to carry his cows through the winter.

Like hundreds of other farmers who have applied limestone to acid soil in order to grow alfalfa and sweet clover, Bormet is reaping the advantages of a very practical kind of health insurance. It is pointed out by C. M. Linsley, soils extension specialist of the U. of I. College of Agriculture. Less fortunate farmers in the state were compelled to buy hay even during the late spring and summer because they had no alfalfa or sweet clover pasture and many will have to continue to buy hay during the winter. The limestone and rock phosphate program carried on in Cook county in past years, however, has meant the difference between having hay to sell and having to buy hay in the case of many farmers, reports Farm Adviser C. J. Barrett.

The testing of Bormet's soil for acidity and available phosphorus by M. F. Fischer, assistant farm adviser, was a money-saving guide in planning the alfalfa crop. One 11-acre field produced a good stand of alfalfa with limestone alone. Soil tests made in this field showed that there already was a good supply of phosphorus there.

An adjoining field, however, lacked both lime and phosphorus. In time all but three acres were limed and in addition half of the field was treated with 1,000 pounds of rock phosphate to the acre. In 1933 that portion of the field which had received phosphate yielded five tons of alfalfa to the acre, while that which got only lime produced three tons. On the three acres where neither limestone nor phosphate had been applied the alfalfa was a failure. This year the phosphated land made a ton an acre more of alfalfa than the rest of the field.

The limestone and phosphate continued to return dividends this year even though it had paid for itself the first year. Approximately \$5 worth of limestone produced three tons of alfalfa the first year worth at least \$36. The 1,000 pounds of rock phosphate, costing \$1, used in addition to limestone, produced an additional two tons of alfalfa worth \$4.

Fruit Growers To Meet At Urbana, December 1-14

Compliance with federal regulations and orders to effect fruit growers of this state is to be the subject of a number of discussions, when a group of the Illinois State Horticultural Society hold their 77th annual winter meeting at Urbana, December 1, 1914 and 14, according to word received by the College of Agriculture, University of Illinois.

For several years increased government restrictions on the amount of sugar residue that may be left on a crop caused an interest to manifest here and there a problem with Illinois growers. To assist the country's growers in coping with this difficulty, W. A. Rutt, chief in charge of the Illinois State U. of I. College of Agriculture, will appear on the program to tell of the experimental work done in residue removal. In addition, Albert W. Kern, of the New Jersey Agricultural Experiment Station, will discuss the services furnished growers in his state in helping them meet the federal regulations.

Progress of the federal government in making code authority and its possible future influence on Illinois growers will be presented by F. H. Thompson, of Elgin, past president of the International Association of Scientific and Technical Workers of the code authority.

Along with the above mentioned speakers will be J. W. Hahn, U. of I. assistant pathologist; W. B. Flint, U. of I. assistant professor of Illinois State Historical Survey and of the U. of I. College of Agriculture; H. W. Howell, superintendent of the state division of standardization and weights, and Fred Heaton, prominent apple grower of New Burnside.

Officers of the code authority in charge of the convention include: George Shook, Decatur, president; G. L. Smith, Elgin, first vice president; Fred Heaton, New Burnside, second vice president; Arthur Holt, Springfield, secretary, and W. S. Perrine, Centralia, treasurer.

41

Empty Stalls In Dairy Farms Are Precious Profits

Empty cow stalls that have been created by cutting out the lower and lower cows have never been so profitable for Illinois dairymen as they will be this winter, says Prof. J. S. Rude, chief in charge of the extension work at the College of Agriculture, University of Illinois.

With the price of feeds continuing to rise higher than the market value of dairy products, and the better producing cows will be profitable enough to pay for stall, Prof. Rude said.

Some Illinois dairymen are even saying they would say that they did not care ago because they have observed on the production records of their cows, have culled out the low producers and left their stalls empty, it was reported.

This is true in the case of at least one member of the McDeviss Dairy Dairy Herd Improvement Association. He cullled a group of 70 cows with an average of 13 pounds during 1913. This year he culled the low producers and left an average of 10 cows with an average of 15 pounds of milk per cow. He is now getting emptying out of the stalls in his herd, this dairymen says with a smile. He is now saving feed costs from the 10 cows in 1913-14 that produced 1000 pounds of milk.

It is not the number of stalls that are filled that is the real test of what are in the that determines the dairy income, Rude is pointed out. At present the relative price of dairy products as compared with the price of feeds is the most important factor. Moreover, in some sections dairy cows are fed with a heavy ration of grain, and if grain or roughage must be shipped in, it is bound to be unprofitable. Under these conditions, it is practically impossible to make a profit on low producing cows.

42

Christmas Candles and Other Accidents As Well As Toys

Christmas is usually the largest sale of the year, but at the same time it is a day in which a large number of accidents are likely to occur, unless certain precautions are taken, says Miss Gladys S. Ward, home management extension specialist at the College of Agriculture, University of Illinois.

In fact three times as many fatalities caused by conflagrations occur in December than in the month of July when the nation celebrates with fireworks, Roman candles and the like. About twice as many people die from burns, scalds and explosions, excepting conflagrations, during the last month of the year as compared with July, and there are twice as many fire and fatalities in the homes this month as there are in July.

Small lighted candles are often put on the Christmas tree, but they also add one of the most serious fire hazards of the holiday season, points out Miss Ward. Light-weight material, tree decorations or even "Santa Claus" himself may catch fire from the candles.

Candles burning in windows with loose curtains are equally dangerous as fire hazards.

The growing complexity of apparatus connected by connecting the floor with electric floor and wall sockets has also added to the danger of burns and fatalities in the home.

Falls from icy streets and walks, especially when they are covered with snow, are among the most common accidents of the holiday season. Although it may give an unattractive appearance, scattering ashes or sand over the ice may prevent a broken arm or leg.

Sharp and bulky toys left on the floor, stairs or in a doorway frequently cause injuries to those stepping on them when the floor is icy. Some children have eliminated this danger by having a small toy box in which the children place their playthings before going to bed each night.

Highly-polished, waxed floors and icy shoes form a combination that increases the danger from falls.

Fatigue from keeping late hours during the holiday season and the hurry associated with Christmas preparations are likewise contributive to home accidents.

-11-

Box Elder Bugs Best Killed By Nicotine Sulphate

Although box elder bugs entering Illinois homes from the fall are not large to foods or fabrics, they are a nuisance that can be best killed by the use of nicotine sulphate spray, according to experts at the College of Agriculture, University of Illinois, Dr. J. T. Flint, chief entomologist of the State Natural History Survey.

These little red and black insects are usually best controlled by spraying in a dry season. More frequently than any other outdoor insect, they are apt to crawl into houses to find shelter from the approaching winter weather. They only wish to obtain suitable protection until next spring when, in the normal course of events, they will leave the house and return to the box elder trees to lay their eggs for the next season's brood.

The fact that the bugs do not seek out wet places in the house makes them all the more difficult to eradicate, explains Flint. Only by using thin bodies with a contact spray can they be killed in any large numbers. The best spray for this purpose, because it kills all the bugs at once, is one containing a table-spoonful of 40-per-cent nicotine sulphate in ten parts of soft water. This mixture has been previously described in a bulletin of the State Natural History Survey. The spray should be thoroughly mixed and applied immediately to the insects on contact. A strong nicotine dust is also effective and is sometimes a finer dust, says Flint.

## THE EFFECT OF THE WIND ON THE GROWTH OF THE WHEAT

At the University of Illinois, the effect of the wind on the growth of the wheat has been studied for many years. It has been found that the wind has a marked effect on the growth of the wheat, particularly in the early stages of the season. The wind has been found to have a marked effect on the growth of the wheat, particularly in the early stages of the season. Prisoners of War in the World War

Altogether, 1,000,000 prisoners of war are in the "penitentiary," to use the term used by the British, and the same number are in the "penitentiary" of the United States. I think the only other countries that have a similar system are France, Germany, and the United States. The United States has the largest number of prisoners of war in the world.

What Causes the Spring Dying of the Fruit in the Districts

The fact is that the spring dying of the fruit in the districts in Illinois is due to a combination of factors. The most important of these is the lack of sufficient water in the soil during the winter and early spring months. This is due to the fact that the ground is frozen during the winter and the snow cover prevents the water from reaching the roots of the trees. The result is that the trees are unable to absorb the water they need to grow and the fruit is killed.

The second cause of the spring dying of the fruit is the lack of sufficient water in the soil during the winter and early spring months. This is due to the fact that the ground is frozen during the winter and the snow cover prevents the water from reaching the roots of the trees. The result is that the trees are unable to absorb the water they need to grow and the fruit is killed.

The third cause of the spring dying of the fruit is the lack of sufficient water in the soil during the winter and early spring months. This is due to the fact that the ground is frozen during the winter and the snow cover prevents the water from reaching the roots of the trees. The result is that the trees are unable to absorb the water they need to grow and the fruit is killed.

The fourth cause of the spring dying of the fruit is the lack of sufficient water in the soil during the winter and early spring months. This is due to the fact that the ground is frozen during the winter and the snow cover prevents the water from reaching the roots of the trees. ## Loss of Soil Nitrogen Since 1910 in Corn

Although Illinois never saw this year the smallest in 24 years, it removed 20 million tons of nitrate from the soil that it could take more than 21 million bushels' worth of nitrate of soda to replace it, according to F. H. Crane, Assistant Chief in Soil Fertility at the College of Agriculture, University of Illinois. For every bushel of corn that is raised, one-half a bushel of nitrate of soda is removed from the soil. The nitrogen that had been removed. This is the minimum loss that is estimated at 10 bushels.

But a slight increase to not more than 21 million dollars' worth of nitrate of soda, for the replacement of soil nitrogen, the only through the use of replace the soil nitrogen of for a crop, provided it is taken care of in the future, Crane pointed out.

Loss of the soil nitrogen of corn production of soil management depends almost wholly on the tillage practices. The extension plants can give, he explained.

Legislation of restoring lost nitrogen. Likewise, there is no feasible means of increase of organic matter for the general farm. Yet this organic matter, which is valuable in many ways for soil condition and in keeping a soil in good working condition, can be built up on the surface and top of lands. When corn takes out most of the plant material, 95 per cent or more of the weight of the plant material is returned to the soil. On the other hand, if the corn stalks are plowed under, the loss of nitrogen from the soil is increased 5 per cent, from 10 to 15 per cent of organic matter.

It is fortunate that man can not remove the plants, explain Crane, for this part of the plant is the only practice means of putting organic matter into the soil below plow depth. In this case, the rotting power of these roots is an important factor in preventing soil erosion and in reclaiming areas already eroded. The loss of plant life in the drainage can be partially controllable by having living plants cover the soil as much of the time as is possible to take up the fertilizing elements.

## Most Hog Rations Deficient Only in Salt and Calcium

Most of the widespread belief, that animals fed to the more than 4,000,000 head of hogs raised on Illinois farms at this time of year contain all the minerals necessary for profitable growth, except salt and calcium, says W. E. Carroll, chief in charge of the College of Agriculture, University of Illinois. Too many producers are so sure that so long as they feed a mineral supplement they can safely neglect other fundamentals of good growth, explains Carroll. There is no substitute for sanitation, balanced rations, good breeding and efficient management, he points out. Minerals are essential, but with the exception of common salt and calcium they are found in ample portions in most hog rations.

-M-

### U. OF I. Develops New Greenhouse Potato Varieties

New and improved varieties of greenhouse potatoes will soon be ready for discriminating Illinois consumers as a result of plant breeding work carried on at the College of Agriculture, University of Illinois, at Urbana, Ill., by W. A. MacMillan, associate chief in horticulture.

In spite of the large quantities of greenhouse potatoes shipped into this State, those produced in Illinois greenhouse during the winter and early spring are in greater demand than ever. The new varieties soon to be introduced to the market are expected to add to the popularity of those grown under glass. The Illinois greenhouse potato is known for its flavor and in contrast to the potato raised in a southern product, a difference which cannot be overlooked.

In developing the new varieties, MacMillan has been crossed with potatoes from China, Poland, Australia and New Zealand. Besides producing well, they are resistant to blight, a serious disease to which many types of potatoes are susceptible.

Illinois greenhouse operators confined their efforts to experimental field varieties due to the expense of transporting tubers to indoor conditions. Peony Best and Globe were the most popular varieties grown at that time, but their late and early winter crops were rather meager.

To assist potato growers with this problem, the U. of I. horticultural department crossed a popular, well-known variety with several well-known field varieties. The Blair Foreman and the Floyd Foreman are the result of 14 generations of selections out of the crosses. Both of the new varieties are maturing at the rate of 1.2 pounds of fruit to the square foot of greenhouse space between December 1 and February 1, which is more than twice the yield obtained from ordinary varieties planted in the same house. The tubers are a little better than those raised in the field. In the field the plants are 1 1/2 to 2 feet high, averaging four ounces each, and the yields to the acre are 10 to 12 tons.

The success of this work has led to further efforts at the U. of I. college, resulting in the new varieties soon to be available to the public.

-11-

### Colorado Hit By San Jose Scale In Course Of A Year

San Jose scale, a dangerous pest to the growth of Illinois fruit groves, has been found for the first time in recent seasons that nine times as many orchards now have scale as there were in 1933, as compared to conditions two years ago. The number of orchards infested is nearly twice as great as it was last year. This was discovered in surveys which S. C. Chandler, assistant entomologist of the Illinois State Natural History Survey, has just completed in cooperation with the College of Agriculture, University of Illinois.

Only thorough applications of oil or lime-sulphur sprays this winter will prevent the insect from taking a heavy toll in the state's 1935 fruit crop, it was said.

Forty-two per cent of the apple and 71 per cent of the peach orchards which were surveyed showed moderate to severe infestation of San Jose scale. This is an average of 2 1/2 per cent of orchards infested, or nearly twice as many as were found in the 1933 survey and nine times as many as in 1932. The increase is believed to be the result of the moderate winter in 1933-34, the few hard frosts in 1934, and during the past year and to a long, mild period in 1935.

## Gain in Activity Will Continue Toward In Near Future

One of the encouraging signs for Illinois farmers is that the trend in business activity and demand is likely to continue upward in a moderate degree during the near future, according to Dr. L. T. Norton, of the department of agricultural economics, College of Agriculture, University of Illinois.

If the total volume of business had been higher during the closing months of 1934, the shorter supplies of cereals, meats and dairy products would have had far more effect on farm prices, according to Dr. Norton, he explained.

Even as it was, prices of Illinois farm products in October and November averaged about 4.1 per cent higher than for the same months of the previous year, according to an analysis which has been made.

Wool and potatoes were the only two of 19 selected products which were cheaper. Subsidies of the 1933 boom in textiles explained why wool was lower, while the larger crop of potatoes accounted for their slump, Dr. Norton said.

Corn and soy beans in particular registered during October and November, the analysis shows. In general the price increases were made by crops which were reduced by the drought and the lower extent of the AAA adjustment programs.

Rice and corn were a little more than twice as high in price in October and November as they were during the same two months of the previous year, while oats and barley were 73 and 81 per cent higher, respectively.

Wheat, on the other hand, was only 25 per cent higher in spite of the short crop. Eggs, beef cattle, hogs and chickens were 10 to 25 per cent higher. Chicken prices were up nearly 50 per cent. Modest increases were registered by other products.

Shorter crops and either actual or prospective shorter supplies of livestock are the principal factors operating to cause the rise, Dr. Norton said. Also contributing to the increase was a slightly cheaper dollar and slightly higher consumer income. Factory payrolls were up 7.5 per cent of 1923-1925 in October-November, 1933, and 20.7 per cent in October, 1934, or about 6 per cent higher than a year earlier.

Compared with those of the two previous months, prices of nine of the 19 products were lower in October and November after allowance was made for seasonal variations. Eight were higher and two were the same.

Rural improvement in consumer income, which has a strong bearing on farm prices, must wait upon genuine revival in the construction industries, Dr. Norton predicted. As yet there have shown only very moderate signs of reviving. The high cost of construction costs probably acts as a brake here, he said.

Rolling St. M. Disease Is Not Fatal With Treatment

Contrary to the opinions of some farmers and veterinarians, the so-called "crystal" disease, which has been killing thousands of horses in Illinois this fall, is not fatal, or nearly so.

This has been established by a series of laboratory investigations made by the College of Agriculture, University of Illinois, it is announced by Dr. Robert Graham, and his assistant, Dr. J. H. Williams.

Although the exact nature of the disease has not yet been determined, it has become so serious that Dr. Williams yesterday reported that they had treated 1,744 cases of it with a recovery rate of 99 per cent. Potassium antiseptic has been used in some cases in the hope of stopping the disease.

However, the nature of the disease of course being not understood, different angles of study are being taken, and with cultures of five different samples of horse blood, found to contain the disease, it was determined that the disease is in every way related to botulism, Dr. Williams said.

"If these findings are confirmed by the next generation, there is no scientific basis for the widespread belief that potassium antiseptic is a cure for the disease," he said.

"In the meantime, the best way to prevent the disease is to keep horses and other animals away from the fields where the disease is still prevalent. If crystals are used or feed, as they are to be used, in the fields, the animals should be kept in stall fields until the crystals are used. Even then the cattle should be kept in stall fields until the crystals are used. Each night for possible symptoms of the disease. If the disease is still prevalent in horses, mules and cattle, the best way to prevent the disease is to keep the animals away from the fields where the disease is still prevalent."

11

Rolling St. M. Disease Is Not Fatal With Treatment

As has been reported in a previous issue of this Extension Messenger, Illinois cattle have been suffering from a disease which has been identified by an expert to help with the disease. This winter, Dr. Robert Graham, Director of Extension, University of Illinois, has reported that the disease is not fatal with treatment.

As a result of the investigation, it has been determined that the disease is not fatal with treatment. The disease is not fatal with treatment. The disease is not fatal with treatment. The disease is not fatal with treatment.

Rather than "crystal" disease, a new name for "crystal" disease along as a result of the investigation, it has been determined that the disease is not fatal with treatment. The disease is not fatal with treatment. The disease is not fatal with treatment.

Edmund Smith of the University of Illinois, who has been identified by an expert to help with the disease. This winter, Dr. Robert Graham, Director of Extension, University of Illinois, has reported that the disease is not fatal with treatment.

George Deubert, a resident of the University of Illinois, who has been identified by an expert to help with the disease. This winter, Dr. Robert Graham, Director of Extension, University of Illinois, has reported that the disease is not fatal with treatment.

## Agricultural Outlook For 1935 and Farm Family Living

The outlook for Illinois agriculture in 1935 is more favorable than it has been for the last few years, but there is still a number of dark spots in the prospect, according to the annual state outlook report released today by the College of Agriculture, University of Illinois.

There are prospects for some improvement in prices of livestock and livestock products in 1935, the report says. Stock prices should be fairly well maintained until the new crops are available. The price of hogs and corn will show further improvement, and this will benefit the small and medium farmers. But some surpluses have been accumulated in the past and the surplus disposal program, the report said.

On the farm, work, development is slow, but the high level of investment in the construction of buildings, where employment is greatest, will generally be slow, the report said.

A brief summary of the essential features of the outlook report follows:  
Farm family living—More money available for replacement of much-needed supplies and equipment. No great change anticipated in prices of goods for family use.

Feed crops—Production expected to increase materially. Feed available, a head, is now much below average. Acreage of chinch-bug resistant crops, such as soybeans, likely to be increased. Spring grains should be seeded early.

Corn—Some acreage increase anticipated. With average yields and fewer livestock, corn market may be expected to decline with the new crop.

Oats and barley—Production of these, particularly barley, precarious, because of chinch bugs.

Wheat—Average yields will create an exportable surplus. This may drop prices to the world level, and large quantities probably would be fed.

Soybeans—Some increase in 1935 acreage is to be expected. Increased production and larger supplies of feedstuffs, which will be available if growing conditions are normal, will tend to lower prices on the 1935 soybean crop.

Dairy products—Long-time outlook is for a gradual increase in prices of dairy products as consumer incomes increase. Marketing of dairy cows is now tending to reduce size of herds.

Poultry and eggs—Poultrymen in position to stay in business should profit from the reduction in flocks that may occur as a result of high feed costs.

Hay and pasture—Retention of old meadows and pastures of fair stands is suggested on account of failure of 1934 seedings.

Forage seeds—Luzerne or grass and clover seeds are about 20 per cent smaller than in the five-year period of 1929-1933. Timothy, millet, Sudan grass, blue clover, red clover and sweet clover seem to be the most seriously reduced.

Hogs—Numbers of hogs for slaughter in 1935 will be the smallest in 20 years. With average yields for the 1935 corn crop, the hog-corn ratio should be favorable to hog raising in the last few months of 1935 and in 1936.

(Continued on Page 2)

Beef cattle--Numbers reduced to approximately the low point in the last production cycle. Low supplies of feed will prevent the usual amount of feeding and will result in higher prices for well finished beef in 1935. Maintenance of established breeding herds that can be carried on home-grown feeds and roughages is desirable.

Sheep and wool--Some increase in prices is expected during 1935 compared with the last half of 1934. Sheep numbers have been reduced by drought conditions.

Horses and mules--Prices for well horses and mules have continued to advance. The rate of decline in numbers is being checked. A good demand for chunks and light draft horses is likely for several years.

-1-

### Illinois Dairymen Juggling Feeds To Lower Expenses

With grain and hay supplies both scarce and high priced, Illinois dairymen may have to juggle their available feeds into unusual combinations to keep their 1,111,000 cows in economical milk production this winter, says W. P. Nevens, associate chief in dairy cattle feeding at the College of Agriculture, University of Illinois.

In sections where the supply of good legumes is limited, better results will be obtained if farmers will feed small amounts of it each day during the winter, rather than give liberal amounts at the beginning and end of the season, points out Nevens.

When silage is plentiful and hay is scarce, the silage may be used to replace much of the hay. Likewise, if the hay is scarce and the silage limited, the hay may be used as the sole roughage.

When farmers use roughage made up of silage and stover mixed with some legume hay, the grain ration should contain about 15 per cent total protein. When good quality clover or alfalfa is available, the grain ration need not carry more than 12 to 14 per cent total protein. If the cattle receive only a low-grade, non-legume hay and stover or straw, the concentrates should contain from 16 to 21 per cent total protein.

Feeding tests at the U. of I. College of Agriculture indicate that cattle do not utilize ground roughage any better than they do the unground.

If plenty of corn is available but the supply of good legume hay is limited, the grain problem is largely one of selecting the high-protein feeds. Cottonseed meal and soybean oil meal are about one-fifth more valuable than linseed meal as sources of protein, while ground soybeans are practically equal to linseed meal. Thus the price of each will be the factor determining the choice. However, it may be well to add some other feed such as wheat bran or middlings, says Nevens.

When grain must be purchased, dairymen should bear in mind that corn and wheat are of equal value, pound for pound, in dairy cattle feeding. Oats, by weight, has about five-sixths as much value as corn. Wheat bran is the best substitute for oats and may be cheaper in price.

Farmers who are able to buy wet brewers' grains should consider the fact that they contain considerable water and usually about one-fourth the nutrients contained in the dried grains.

### Preventing Falls Would Save Lives, Says Bureau Head

A New Year's resolution every Illinois homemaker might well list at the head of her list would be to help prevent falls in the home, which in one year have killed as many as 13,700 people, it is suggested by Miss Gladys J. Ward, home management specialist at the College of Agriculture, University of Illinois. If no falls in homes which in one year killed 13,700 people might have been prevented, Miss Ward believes.

### Supply Of Forage Seeds Only Half Of Five-Year Average

Only about half as much grass and clover seed as in the five-year period 1930-1934 will be available to farmers in Illinois and other states when the spring planting season opens, according to J. C. Hackleman, crops extension specialist at the College of Agriculture, University of Illinois.

About 107 million pounds of such seeds are used annually in the United States, 56 million pounds being sown in Illinois. The 1934 production plus the carryover from the old crop, however, totals less than 150 million pounds, or about 44 per cent of normal needs, it was reported.

Timothy, millet, sudan grass, alsike clover, red clover and sweet clover, in the order named, show to be the most seriously reduced.

The outlook for the supply of grass and clover seeds as summarized in the annual state outlook report just released by the agricultural college follows:

**Alfalfa**--Supplies of seed will probably meet normal planting needs, despite a 1934 production well below average and an unusually small carryover. An unprecedented heavy seeding of alfalfa was made in the late summer of 1934, with the probable result that a somewhat smaller than normal seeding will be made during the coming spring. If spring seedings are normal there will be a deficit of about 1 million pounds of native seed.

**Red clover**--Available supply bears 29 million pounds or nearly the average annual consumption in this country. The 1934 production amounted to 36 million pounds as compared with 57 million in 1933 and 74 million in 1932.

**Alsike clover**--An unusually small carryover and a short 1934 crop have made the supply of this seed extremely small. Prices are likely to hold fairly high.

**Sweet clover**--Although stocks are the smallest since the crop began to be grown extensively, the available supply is considered about equal to the average annual consumption. Prices will remain strong, but not so high relatively as either alfalfa or red clover seed.

**Lespedeza**--Seed production in 1934 is estimated to be one-third less than in 1933. Seedings last spring were much larger than in previous years, but the increased acreage was used largely for hay and pasture and less seed was harvested.

**Timothy**--It is estimated that approximately 9 million pounds of this seed were harvested in this country in 1934 as compared with the four-year average production of something less than 69 million pounds. The available supply is some 36 million pounds short of normal annual seed needs.

**Kentucky bluegrass**--Seed supplies seem to be sufficient to meet normal sowing requirements. The 1933 carryover was large enough to overcome the small 1934 crop.

**Redtop**--Seed is ample to meet all normal sowing demands.

**Millet and sudan grass**--Supplies for 1935 seedings are among the smallest on record. Available sudan grass seed is around 13 million pounds or about 55 per cent of average annual consumption.

The outlook report suggests the retention of old meadows and pastures where stands are fair and the conservative use of short seed supplies. There probably will be a deficiency of hay produced in 1935, owing to drought and close grazing of meadows in 1934 and shortages of seed with which to make new seedings. Foreign resources will be further depleted by probable early grazing of pastures next spring, the report points out.

## Get May and June the Only Hope Against Chinch Bugs

Chinch bugs, which took an estimated toll of more than \$1 million dollars in the 1934 Illinois corn crop alone, threaten to be worse over most of the state in 1935 unless May and June are cold and wet enough to kill them off, according to officials of the College of Agriculture, University of Illinois.

W. B. Flint, chief entomologist of the Illinois State Natural History Survey and of the Agricultural College, has outlined three lines of attack which farmers can be expected to follow in combating the bug.

The first step, he says, is to plant the corn in rows of crops on which the chinch bugs do not feed, such as soybeans, alfalfa, clover, cowpeas, buckwheat, radish and other winter crops.

Second, crops on which the bugs do feed should be so arranged as to avoid, insofar as possible, a cold winter and a hot and dry spring. This will reduce to a minimum the number of rods of barriera that will be needed between small grain and corn fields when the weather is so corrected.

Third, Flint says, the weeds only should be plucked by themselves wherever possible, and less should be plucked in corn.

The last sound method, he says, is to plant winter wheat, rye, timothy, rye and oats.

Up to the present time the only material that has been used to materially reduce the numbers of chinch bugs in the state, Flint reported. Further, there is little likelihood that the weather of the winter will kill the bugs or their hibernating eggs. It is possible, however, that a winter that is 25 percent of the bugs were killed by the winter, he said.

With an early start, chinch bugs are still very abundant in most of the area in the state, he said. They are still very abundant in the western Illinois and southern section, and are more of the counties of DeKalb, Jersey, Green, Pike, Adams and Scott.

There is also a large number of chinch bugs in the western part of the state in DeKalb and Scott counties until now, and it is possible that very serious damage will occur, Flint said.

Over the rest of the state, they are still very abundant in White and Lawrence counties, and the south of the White and Lawrence counties are more abundant than they were last year. In May and June in 1934 the chinch bugs are now in the winter quarters and the eggs are now in the winter quarters of 1935.

The bugs are now in the winter quarters and the eggs are now in the winter quarters. Many more of them than in any other year are found in the winter quarters.

There is very little chance of doing any effective plucking before the first of May, and it is doubtful if the best plucking that could be done would destroy a greater percentage of the bugs over an area as large as a township or county, it was said. With the numbers now known to be in the winter quarters, a 10 per cent reduction will not make any appreciable decrease in crop damage this coming year, the authorities say.

Korean Lespedeza Grows In Grains Making Good Emergency Hay

Faced with the problem of providing an emergency hay or pasture crop in 1935, because of the drought last summer, Illinois farmers may find the solution by seeding Korean lespedeza on winter wheat or with oats this spring, says J. J. Pieper, associate director in crop production at the College of Agriculture, University of Illinois. Although the production of lespedeza seed in 1934 was about a third less than in 1933, there is probably enough to handle all demands in 1935, it is believed.

More than 100,000 acres of lespedeza were grown in Illinois in 1934, an approximately 400 per cent increase in the preceding year, it is estimated. Thus with such a large acreage increase in the state, this comparatively new legume has become one of Illinois' rapidly growing crops.

Korean lespedeza may also be grown alone on land that is not too woody. This is especially true on the light-colored soils of southern Illinois where weeds are not serious. In this case the crop is seeded on high nitrogen stable. When lespedeza has not been grown before, the seed should be inoculated.

To make a hay crop the first season, lespedeza should be sown at the rate of 25 pounds to the acre, either with or without a companion crop. This may be done in early March on winter grain or at the time spring grain is planted. When sown in small grain about one-half ton of hay may be expected for first cutting, while if sown alone the hay yield may total two tons or more.

When Korean lespedeza is seeded on winter wheat or with oats, the grain may be cut as hay or allowed to ripen. If the latter is it, two paddocks will have two emergency hay crops, the wheat or oats in May or June and the lespedeza in late summer or fall.

Where lespedeza was grown in 1934 and a good volume of seed is available this year, the field may be disked and planted to oats, wheat or spring corn again this spring. Tests at the U. of I. College of Agriculture have shown that the disking will increase the yield of lespedeza materially, while the companion crop may be planted and harvested normally. Thus the farmer may produce two crops on the same land in 1935 with but little preparation and expense other than the cost of the grain seed.

Summer Gardens a Profitable Crop Caused By Lack Of Planning

Lack of planning is the indirect cause of all too many failures of Illinois gardens, which if properly managed might easily be the most profitable source of the farm, says I. A. Somers, vegetable garden extension specialist at the College of Agriculture, University of Illinois.

Detailed plans made well in advance of planting time make it possible to take advantage of favorable weather conditions, give more efficient use of the garden area and often reduce the labor required, all of which add to the profitability of the garden.

Proper planning can best be done when the frost has melted and the birds have arrived. A pleasant evening or two can be spent in selecting the varieties to be sown and in making out the seed order. Then when April comes, the gardener is ready to take advantage of the first good planting days.

In January a drawing can be made of the plot, showing the location of the different vegetables as they are grouped according to their climatic and soil requirements. The succession of greens, salads and bell peppers, black and white beans, as well as the needed quantity of each. The varieties to be planted in view of the crops to be canned, those to be stored and those to be used fresh.

-M-

Stopping Insect Damage Seeks to Rise In Food Cans

Any increase in the cost of food which the winter may bring can be partially offset by stopping the waste now being caused by insect damage to dried food products in homes, stores and other heated buildings, says M. E. Farrar, research entomologist of the Illinois State Natural History Survey.

Contrary to the belief held by many people, under certain conditions the damage done by insects to stored beans, peas, rice, breadstuffs, peanuts and all dried fruits may be just as great in winter as summer. In fact it is difficult to find a home, grocery, warehouse or factory that does not have at least a small infestation of insects feeding upon dried food products at some time of the year, Farrar pointed out in a report to the College of Agriculture, University of Illinois.

A forgotten candy bar, a piece of chocolate, a bag of peanuts or a slice of dry bread will furnish ideal breeding material for several of the most troublesome household pests. Examining a food package to make sure that it is free of insects before placing it in a cupboard is a good precaution. Sealed packages may contain insects, but this is less common than in the case of bulk goods. Insects in any food product can be destroyed by heating the material in a pan for three hours at a temperature of 135 to 140 degrees Fahrenheit.

When possible, large quantities of food products should be stored in tight containers in unheated rooms or buildings. Low temperature prevailing throughout the colder months of the year will reduce the activities of most insects.

Beans and peas to be used for seed can be protected against weevil damage by mixing the seed with hydrated lime at the rate of 10 pounds of lime with each bushel of seed. When large quantities are stored in tight bins, mixing a heavy deposit of lime into the upper six inches of the beans will protect them from insect damage. The lime does not affect the germination and may be washed off of the peas or beans before they are used for human food.

-M-

Winter Pasture An Aid In Utilizing Poor Roughages

In spite of the fact that fall and winter pastures in Illinois have exceeded all expectations, livestock producers will do well to conserve them as supplementary feed to cheap roughages that may be available on the farm, according to F. T. Robbins, livestock extension specialist at the College of Agriculture, University of Illinois.

After the arrival of generous rains in late August, pastures made unusually heavy growth during the fall, and when not covered with snow will still supply considerable winter feed. Furthermore, livestock getting pasture can use poor roughages to greater advantage than when given the low-quality feed alone, points out Robbins. Cattle will graze stalk fields more closely and is better on them, if the animals have the run of an old pasture at the same time.

Farmers are warned, however, that too much a reliance on winter pastures might prove to be false economy. There will probably be a deficiency of hay produced in 1935, as a result of the drought, too close grazing during the summer and a shortage of seed with which to make new seedlings. Thus conservation of all roughages and pastures is an important consideration this winter. Many pastures were grazed too closely in 1934, and too heavy grazing during the coming spring months might add further to the destruction of forage resources.

## Dealing with the Milk Problem in Spring Months

Along with the milk problem for the coming year in Illinois is the problem of disposing of the surplus milk produced by the 1918 crop. In the opinion of W. W. Foster, chief instructor in the College of Agriculture, University of Illinois, the best way to dispose of the surplus milk is to use it for the production of all kinds of milk products. The surplus milk should be used to produce good cows and other milk products for the next year's production of the era.

The surplus milk should be used to produce all kinds of milk products. The surplus milk should be used to produce good cows and other milk products for the next year's production of the era.

## Franklin Doolittle Explains Farm Building Program

With a budget of \$100,000 for 1919, Illinois farmers have managed to adopt one of two methods in carrying out the program. The value of the program is \$1,000,000, says W. A. Foster, rural architectural specialist at the College of Agriculture, University of Illinois.

Many farm owners will probably, at the present time, be more cooperative in the course of the program. They will see the value of the program and the better improvements will be made as each becomes available. Owners will be more cooperative, proper care taken in doing the work, and the program will be more successful. The program will be more successful if the owners are more cooperative.

Alfalfa Crops Not Favored in Northern Districts

Alfalfa, sometimes called the "Queen" of forage crops, will be even less popular in Illinois during the coming seasons as a result of its performance in the 1934 drought, according to J. B. Miller, assistant in soil experiment fields at the College of Agriculture, University of Illinois. Last year's dry weather kept the state's total crop production down to the lowest level ever known, but it seems to have been a trial for Illinois alfalfa fields, as well.

Despite the drought, alfalfa was produced in normal, with some fields actually yielding more than the average for the past two decades. It is estimated that there were more than 850,000 acres of alfalfa in the state last year, and on many farms it proved to be a lifesaver for dairy herds.

Records at the Mt. Morris soil experiment field in Ogle County, operated by the U. of I. College of Agriculture, reveal that in a rotation in which alfalfa is continued for four consecutive years, the average yield for the past 20 years has been 3.81 tons to the acre a year. The local alfalfa yielded 3.29 tons. These results were secured on land which had been in a corn pasture.

Under similar soil conditions at the Mt. Morris field, the long-time average for red clover yields ran 1.32 tons to the acre a year. In 1934 the red clover harvest fell to 1.1 tons. This was an unusually good red clover yield under the drought conditions of northern Illinois last season, and for fields produced here than a ton to the acre. Even the alfalfa yield at the Mt. Morris field, only 85 per cent of the long-time average for red clover, was better than alfalfa crop turned out to be better than the red clover crop.

An excellent pointer in northern Illinois, alfalfa is also a better crop here as compared with most other crops that crop farmers who have left crop production to this region to cultivate. Since alfalfa, however, requires a well-irrigated soil to be best and is irrigated with available water hours, Miller pointed out.

Plant Houses and Benches for the Winter Months

Plant houses are a little neglected in Illinois, but they are a valuable winter gardeners' means to grow their seedlings for the 1935 growing season, according to W. A. Jensen, vegetable specialist and horticulturist at the College of Agriculture, University of Illinois.

For many gardeners a 16 by 16-foot house is a good size. It should be on the north side. It requires six concrete blocks on each side of the roof and one along the lengthwise to form a rim and wall. The houses are built to receive 11 and 12 ft. possible, and usually run from north to south. The north end is left open, except a screen of boards, while the south end is made of glass, with the exception of the door.

Heat is supplied by an inexpensive stove set up at the north end of the house. The pipe rises straight to the ridge-pole and then runs the length of the house to emerge at the south end. Houses longer than 16 feet are ordinarily heated with electricity, if the available current is not too costly. Otherwise, a single hot water system or two stoves are used. Being 6 ft. wide, the house is filled with benches 4 by 16 feet each, except a sufficient space is left at the north end or the stove. This amount of bench space may be supplied by a first-class set of racks during the germination period. Seeds, flats, pots and other things are stored under the benches.

## Corn Supplement in Pig Feeding Pays Higher Premium

With an increase in the price of hogs, about 40¢ will be added to premium this winter. It is therefore profitable to raise pigs with a view to fatten them for fattening hogs, and the best way to do this is to use a supplement of corn in the culture, and not to use a supplement of alfalfa. It is found that the best way to raise the hog is to use a supplement of corn in the culture.

One hundred pounds of good feed is an equivalent of a ton of tankage which would cost about \$1.50, and a ton of corn in the feed of a pig weighing 100 pounds each at the beginning of the feeding period. As a result of results of tests conducted by the Agricultural College, University of Illinois, 100 pounds of tankage would cost \$1.50, and a ton of corn in the feed of a pig weighing 100 pounds would cost \$1.50.

In feeding it is practical to let the pigs have all the corn they want from a life-long supply of tankage. However, when the corn is of good quality, as it is in some cases, it is better to let the pigs have a smaller quantity than they actually need for several reasons. Their actual consumption will be limited the amount of corn in the tankage, the correct proportion of corn to tankage, by mixing the corn with tankage, and the correct proportion of corn to tankage.

For a tankage supplement of 100 pounds it will be the most economical method, but the best will be to use a smaller quantity for all pigs to be fed so that all will be able to eat it. It is advisable to use a smaller quantity of tankage according to the weight of the pig and a higher proportion of supplement in their ration to make the supplement.

When a pig is hand-fed, pig weighing 10 pounds or less should get from 10 to 15 pounds of feed each day of corn and 10 to 15 pounds of tankage, and 10 to 100 pound pigs should get 8 to 15 pounds of tankage, and 15- to 30-pound hogs should get 8 to 10 pounds of tankage for each bushel of corn.

At present prices a supplement composed of 3 parts tankage and 1 part alfalfa meal by weight is probably the best economical, according to Dr. Campbell. Certainly the alfalfa meal will be of much more value in raising a protein supplement to feed the pig. Their contribution to the value of a mixed supplement is not great enough to warrant including them in the best tankage.

If the mixture of 3 parts tankage and 1 part alfalfa meal by weight is used as the protein supplement, it should be fed at the rate of 18 to 19 pounds for each bushel of corn for pigs weighing up to 100 pounds. Those weighing up to 100 pounds should get 13 to 15 pounds of the supplement for each bushel of corn, 100- to 150-pound pigs should get from 8 to 9 pounds of the supplement for each bushel of corn and those weighing 150 to 200 pounds should get 4 to 5 pounds.

New Experiments May Help Revive Red Clover Growing

What was once the principal and about the only legume crop in Illinois now is headed for a comeback as a result of new experiments being conducted by plant breeders of the College of Agriculture, University of Illinois. Red clover is the crop. The plant breeders are uncovering new possibilities for improving it so that it can withstand the hazards which have slowly been killing it out.

Illinois was once one of the greatest states in the production of red clover, but plant diseases, insects and adverse weather have cut production so severely that the state hardly ever has even enough seed to meet its own needs. Red clover failures also have brought on feed shortages with subsequent losses to dairymen and stockmen.

Preliminary work by plant breeders at the U. of I. College of Agriculture has revealed that there are extreme differences among red clover plants in characters that are important from the standpoint of successful production of the crop. Hardly any two plants have been found to be alike. Also the difficulties in red clover improvement work have been more clearly recognized. However, it is believed that plants can be selected and new strains built up that will be superior and useful in overcoming present hazards, it is reported by Dr. C. M. Woodworth, chief in plant genetics at the college.

In the past plant breeders have avoided the red clover crop because it is so hard to propagate under conditions of controlled pollination. The plants are almost entirely self-sterile, insects being depended upon for pollination under field conditions. Hand pollination can be done on a small scale, however.

Evidence of neglect of this crop by plant breeders is seen in the few distinct strains now existing. Red clover seed is a conglomerate mixture as to color and will produce all types of plants. When the plants are spaced so that their distinguishing characters can be observed, they are seen to differ in leaf markings, flower color, growth habits, winter hardiness, resistance to disease and pest infestation.

-11-

Ordering Garden Seed Early Cuts Production Expenses

Always a good practice under normal conditions, ordering garden seed early takes on greater importance this year in view of the possibility of a scarcity of a number of vegetable seeds, says B. L. Weaver, olericultural specialist at the College of Agriculture, University of Illinois. Weather conditions were none too favorable for garden seed production last summer. This not only will make it advisable to order early but also to check up on any holdover seed that may be on hand from previous seasons. Such seed sometimes gives a higher germination test than new seed.

It is impossible to predict the hazards of the coming season, but if the vitality of the seed is known, it will be possible to get an adequate stand at less expense than would otherwise be possible. Higher germinating seed may be more expensive, thus making a material saving in the cost of seed as well as in the expense of thinning out the rows later on. Ordering early allows plenty of time for testing and adjusting in case the seed is of low quality.

Gardeners have likewise found that keeping a seed inventory is helpful in determining the seed needs each spring. When seeds are purchased the date is written on the packet, and in an inventory book is entered the name of the variety, amount of seed bought, the cost, the name of the grower and the date of purchase. A glance at the list in January reveals information that will assist in making up the present year's seed order.

-11-

Leaf Curl Sprays Kill Frost at Peach Crop Experiments

Bloom buds on Illinois peach trees this winter give prospects for the largest harvest since 1931, and growers can protect their chances for a crop by spraying orchards now to ward off possible leaf curl damage this spring, says Dr. H. W. Anderson, chief in pomological pathology at the College of Agriculture, University of Illinois. The 1931 crop totalled 4,300 bushels of fruit valued at \$3,120,000.

Early spraying is essential because the fungus which causes leaf curl lives over the winter on the buds, leaves and may start infection during warm days in February before the buds are completely open. Dr. Anderson pointed out. The spray can be applied at any time when the temperature is above freezing and there is no danger of a cold wave. Some freezing at night will do no harm. The recommended spray at the rate of one gallon of the liquid concentrate to eight gallons of water may be used, but an oil spray in Bordeaux mixture is preferable.

When 100 gallons of the oil Bordeaux mixture is prepared at home, the tank should be partially filled and eight pounds of powdered copper sulphate added while the agitator is running. Eight to ten gallons of kerosene is then mixed with a little water in a pail until it forms a thick paste, after which it is poured into the tank. In another container three gallons of steam oil emulsion is mixed with an equal amount of water and poured into the tank. Eight gallons of water is then added to make up 100 gallons. Following a few minutes' agitation, the spray is ready to use. Even, twig on the trees should be covered with the spray to insure control.

If spraying is neglected and the weather turns favorable for the development of peach leaf curl, the bright outlook for 1935 peach returns might easily be turned into complete failure. If it is cold and rainy as the buds expand this spring, the infection is likely to be severe, while if dry, warm weather prevails for a week or so, no great damage will be done. Since it is not possible to predict the weather accurately, it is never safe to omit leaf curl spray. This year it is especially important to apply dormant spray, for San Jose scale is abundant on many Illinois orchards and the same application may be used to check scale and leaf curl.

-17-

Forest Extension for Illinois Would Eliminate Jobless

Non-competitive work could be provided for thousands of Illinois people now on relief roles, if much of the state's unutilized woodland was converted into managed federal, state, municipal or private lands and forests, in the opinion of E. E. Sawyer, forestry extension specialist of the College of Agriculture, University of Illinois and the Illinois State Natural History Survey.

Illinois has more than nine million acres of submarginal land that is better adapted to the production of areas of increased value than it is to growing strictly agricultural crops. If properly managed on this land, this acreage would in time not only pay satisfactory returns on the investment, but also would relieve the unemployment situation in certain areas of the state, Sawyer said.

On federal-owned timber tracts, forest products are sold to the Illinois Forestry Department and are being used to such improving roads, clearing down lines, erecting fire towers, constructing telephone lines and increasing the production of timber lands of the state. If the remainder of Illinois' potential forest land could be equally well managed by the state, by counties, by municipalities or by private owners, thousands of men now out of work could be given permanent employment in the forests.

## Evidence Found That Local Markets Favor Live Stock

Despite reports to the contrary, there is ample evidence that the so-called "bussed" local live-stock markets, and the so-called "direct marketing," have increased the general level of hog prices. This is the result of studies which have been published in a new Bulletin by the Extension Station of the College of Agriculture, University of Illinois.

The title of the Bulletin is "Evidence of the Extension Station is directed to the fact that in 1927, when a week was set aside for work on hogs in the state, the receipts of Illinois hogs in the market totaled \$47,402, 000. The receipts have averaged \$4,000,000 a week since that time. For the period from 1924 to 1928, R. L. Ashby, extension economist in live-stock marketing at the college, who conducted the studies, is rather emphatic in his conclusion. It is titled "Local Live-Stock Markets in Relation to Carr-Salt Hog Marketing."

For live-stock men to base their live-stock marketing on a centralized system during the ten years that local markets have been developing, Ashby points out, is "a situation which today, stockmen are supporting and maintaining the so-called markets—local and terminal—the latter tending to be favored, he said.

Local markets have to be maintained at a general level in hog prices. Because they have reduced hog receipts at terminal markets and sent a larger and larger proportion of hogs direct to the packers, they have lowered the profit on a head of hog at the terminal markets and they have reduced the participation of the local dealer, he said.

Local markets have to be maintained at a general level in hog prices. Because they have reduced hog receipts at terminal markets and sent a larger and larger proportion of hogs direct to the packers, they have lowered the profit on a head of hog at the terminal markets and they have reduced the participation of the local dealer, he said.

Along with the tendency to check hog prices, there is a disadvantage of local markets, and less assurance of accurate weights under non-competitive scales and grading, no assurance of payment, often no facilities for the disposal of waste, and the probability of failure to exercise to stockmen their full share of the savings of a local marketing operation.

Advantages of local markets, as shown by Ashby, include convenience, prompt returns, some apparent saving in marketing expense and the avoidance of risk of price change while the hogs are on the way to market.

Stockmen and stockmen's organizations are the main point of contact in the operation and control of local live-stock markets, he said.

"Stockmen could solve their live-stock marketing problems if they are sufficient in all organized and agreed on a marketing program. Important factors are not to organize.

"Terminal marketing costs could be reduced in two ways: (1) by concentrating live-stock consignments in the hands of a few smaller wholesalers, and (2) by enabling the remaining ones to operate both more economically and more efficiently.

and (2) by persuading stockmen to cooperate more fully in the operation of the only the result of facilities required or accepted prior to the operation and releasing the remainder for other uses.

(Continued on page 2)

"Local marketing cost can be reduced by decreasing the number of local markets. With present-day road and traffic facilities it is their object to get in as many local markets as the livestock industry is now supporting.

"Railroads could aid in the solution of the local market problem by starting terminal markets in-transit routes with provision of skins of ownership. It is improbable, however, that such action will be taken.

"Factions could probably correct in qualities and prices were it not for conflicts of interest between export and producer groups. Moreover, from the standpoint of the stockman, it is desirable that the problem be solved by other means.

"Finally, the U. S. Department of Agriculture, under provisions of the Agricultural Adjustment Act, could institute initiative such as would be necessary to deal with existing and other conditions. There is no prospect of early remedy from other sources."

-11-

Soybean Quality Drawing Attention As Crop Expands

Illinois' rapid rise to the national lead in soybean production and the prospects for a still further increase in acreage during the coming year are drawing attention of farmers and plant breeders to marked differences between varieties of this crop, according to Dr. J. H. Woodworth, chief in plant breeding at the College of Agriculture, University of Illinois.

The record crop of nine and a half million bushels in Illinois in 1934 was valued at more than eight million dollars and represented 34 per cent of the national production.

Soybean varieties have been found to vary not only in seed color but also in many other characters affecting their commercial production, Dr. Woodworth said. These differences will become increasingly important as the production of the crop expands, he pointed out.

"One of the important characters in which varieties differ is in the number of seeds a pod. There are some pods with only one seed, some with two seeds, others with three and still others with four. Usually there are very few one-seeded and four-seeded pods in a given variety. Varieties also differ in the proportion of the different-sized pods. The Ito Sun, for instance, is predominantly two-seeded type and the Illini, a three-seeded type.

"In experiments on breeding soybeans a type was found with a very high percentage of one-seeded pods. Two or three newly introduced varieties from the U. S. Department of Agriculture show a higher proportion of four-seeded pods than any commercial varieties now being grown. Experiments show that these varieties bred true for the particular proportions found, indicating that the character is inherited.

"Contrary to what might be expected, the varieties having a high proportion of four-seeded pods are not a good seeders. Many varieties with a majority of two-seeded pods. The four-seeded types usually produce small plants bearing a much smaller number of pods than the taller-growing, high-yielding two-seeded varieties.

"Furthermore, it is difficult to combine the four-seeded character of a variety with the good characters of another variety. This is only one of the difficulties in improving soybeans for a still more important place in American agriculture."

-12-

Home-Butchered Pork for Seldom Out of the Pantry

Farmers in Illinois have been butchering a much larger number of hogs worth of their own pork annually during recent years, but the knack of cutting a hog carcass to the best advantage is still a mystery to many of them, says Stuart Bull, associate chief instructor at the College of Agriculture, University of Illinois.

"Many farmers still spoil the best cut of pork, the loin, by splitting the carcass down both sides of the back bone with a cleaver or the saw. The latter should be split down the center of the backbone with a sharp knife, and the ribs are still very good.

"The carcass should then be allowed to cool to a temperature of 40 degrees for at least 24 hours before it is cut. The meat is best done in a cool place where the meat will not freeze. The head is first cut off by making a saw cut through the atlas joint where the head joins the neck. It is pulled out from the back bone, flattened out or being pounded with the flat side of a cleaver or with a board and then squared up with the knife for bacon or for ham bones.

"The half carcass is then laid on its side and the feet cut off just above the knees and the hocks. The shoulder is cut off with a square cut between the third and fourth ribs. The neck bone and the ribs are then taken out. The upper part of the shoulder, or the 'Forequarter' is cut off two fingers above where the shoulder blade shows on the rear edge of the shoulder.

"The 'clear place,' the leaner part on top, may be cut off and used for lard or cured for bonyork. If it is to be cured, some of the lean should be taken off with it. The Boston neck is cooked in lard or fat or chops, it may be cured or it may be boned and used for sausage. The lower part, or 'picnic,' may be boned for sausage or cured. The entire shoulder may be cured without division, but the results will be better if it is separated into Boston, clear place and picnic.

"The hock is cut off about three inches in front of the pelvic bone, with the h-bone, the saw being held perpendicular to the line of the hind leg. The hock is then trimmed so that there are no loose, thin, ragged pieces of meat on it. The tail and flank also are trimmed off. If the hock is very fat, the skin and some of the fat may be removed from it. However, about one-half inch of fat should be left over the lean. Hams are usually cured.

"The leaf fat is then stripped out of the carcass for lard. The leaf fat, including both the loin and the fat back, is cut from the belly by a wide saw cut. The ribs from the point just below the back bone, where the shoulder was removed, to the joint just below the large muscle where the ham was removed.

"The 'fat back' is removed from the loin with a sharp knife, a thin layer being left over the back muscle. The fat back is used for lard. The loin may be cured for roasts or cut up into chops. In thin loins the fat should be left on the ribs, the back bones and ribs removed and the hocks and neck cured and sold as lard.

"The spare ribs are cut from the belly with a sharp knife. The belly is then trimmed so that all corners are square, and the fat is removed and all ragged pieces removed. Enough meat is trimmed off the belly to make a ham, the picnic, the front or brisket, the ribs and the neck. The neck is cured and used for sausage and lard. The ribs and belly are cured and sold as lard. The trimmings should be used for lard and all deep-frying should be done with the trimmings should be used."

## Secret of Better Flavor Discovered In U. I. Tests

The secret of enhancing the flavor and aroma of butter, a practice which has been in use for almost 50 years, has been worked out in the laboratories of the College of Agriculture, University of Illinois. It is announced by Dr. H. A. Ruess, head of the dairy department. The process is now to be applied on a more direct and more effective method than has heretofore been possible, he said.

Believed to have "great possibilities," the discovery essentially may profoundly affect the billions and billions of pounds of cream and butter manufactured annually in the United States. Plans are being made to patent the method and give it to the dairy industry for whatever benefits it may bring producers and consumers in the way of a higher quality and more desirable product, Dr. Ruess said.

Working with him in the laboratory on the new method was P. J. Ramsey, a member of the college dairy manufacturers division. The process involves the distillation of the ordinary "starter" used in butter making. Concentrated quantities of the volatile flavoring principles which impart the desirable aroma or bouquet to butter are obtained in the distillate.

Their finding is another and the latest improvement in the use of cultures, or "starters," in cream, a practice which has been employed for many years to develop flavor and aroma in butter. The Danish bacteriologist, Storch, who began his work in 1884, was the first to investigate butter cultures. Four years later the use of such cultures in cream, "trigenin" became a part of the commercial butter-making process.

Subsequently other investigators established the fact that two other organisms besides the one commonly present in starters were necessary for successful results. Until later it was proved that these organisms changed the citric acid of milk into acetylacetyl acetate. This in turn was converted into the volatile chemical compounds which produce the aroma and flavor.

However, attempts to intensify the flavor of butter by the addition of synthetic compounds of this character have been regarded as adulteration and therefore an illegal practice.

The method developed by Ruess and Ramsey not only makes it possible to isolate the flavoring principles from a starter but also to increase the content of them in that starter.

When the distillate obtained in the process is added to cream, the flavor and aroma are greatly intensified without increasing the acidity, or citric acid content, of the cream. Sweet cream treated in this manner produces a butter that had the high aroma and flavor of that made from ripened cream, yet had low acidity. The distillate can be added directly to the butter to obtain similar results.

Whether Lard For Meat Or Fatens In Spring Meat

Although some people are still sceptical, neither fat or lard have anything to do with curbing in the new-curing of the 150 million pounds or more of corn which Illinois farmers bumper annually, according to Professor Chester Bull, associate professor of meat at the College of Agriculture, University of Illinois. When dress lard, however, with the method which is used, he said.

The ideal temperature for curing meat is several degrees above freezing. Usually a cold room in the basement is the best place. The meat, cut often across are the hams, shoulders or picnic and bellies or loins. Cuts may which can be cured are necks, or hams square, ribs, loins, loins and boneless loins or backs.

A standard recipe for curing hams is 2 pounds of salt, 1 pound of either granulated or brown sugar, 5 ounces of nitrate and 5 gallons of water for each 100 pounds of meat. The salt, sugar and nitrate are mixed together and a coating rub is all over the meat, after which it is allowed to lie in a cool place over night. The remainder of the salt mixture is then mixed in the 5 gallons of water, boiled and the water allowed to drip off. After the solution has cooled, the cure is skimmed off.

The meat is packed in as tight a pack as possible, skin side down, in a clean, scalded stone jar or hardware barrel. The top layer of meat should be placed skin side up. Hardwood staves are then placed across the top and weight put on. The brine is then poured on, care being taken to see that the meat is completely covered.

Hams and shoulders should remain in the brine three days or a little longer for each pound they weigh. A 15-pound ham will be nicely cured in 45 days. Smaller cuts, such as bacon, picnic and loins, should be given a similar cure by being removed after two days has been allowed for each pound. The jar should be washed and repacked at the end of the first week and again at the end of the second week, the same brine being used in both cases for the recuring.

As soon as the meat is removed from the cure, all salt should be soaked two to three hours and thoroughly scrubbed to remove the excess salt. This is important. The meat should then be packed, strung in the meat house and allowed to dry over night.

Too Many Farmers Have Failed In Springing

About three-fourths of all dairy cows in the United States are too old to produce milk and but a part of the rest are young and well-bred and are not well bred prices, according to observations made by Professor W. H. Frasier, professor of dairy farming at the College of Agriculture, University of Illinois. In some sections as high as 40 per cent of the cows are too old, he said.

With feed so scarce as it is now, dairymen should do their best to get rid of that many of them have been doing during the hard times, he says. Instead of buying more cows in an effort to bolster a cash income, dairymen should get rid of all but their better cows, he said.

If the cows that are now being sold are not well-bred and the feed thus saved were given to the best-bred cows, the dairymen would get much better than the herd raising for a while would be doubled. Dairymen should continue to feed their good cows this winter and spring and to buy only the best calves and the high-priced ones it is now.

Soybeans Meeting Emergency In Wintering Range Horses

Many thousands of Illinois horses have had their first taste of soybean hay this winter. They are on farms where soybeans were grown last summer for the first time. These horses have thrived on soybean hay just as other thousands of Illinois horses have done elsewhere and have done it in the past. A few Illinois farms have used soybean hay almost exclusively for their horses during the past 4 years. Results have been uniformly good. The only precaution is to feed only a moderate amount of this rich hay, so that the horses are all but the coarsest steers.

Soybean hay has had a great effect on horses this winter. In some cases the horses have had plenty of this hay and have come through the winter in very good condition. This year's corn and alfalfa appear to be very dangerous horse pasture, and the writer has been called upon to warn against their use for horses this season. In some dangerous areas which have had the run of stalk fields did better where soybeans had been planted in the corn. It is noticeable, too, that horses which are getting much field ration, straw or dried grass which is still left in the fields thrive much better if they also have a small feed each night of soybean hay or other legume roughage.

One of the difficulties this winter is the thin condition of many farm horses because of the scarcity of good feed. The use of soybean hay or other legume hay from now on through the season will help these thin horses to improve. Also by March 1 it will help the horses get ready if they are stabled at night and fed a little grain. If they get out again in the fall they will be able to feed a small amount of the crop of beans during the fall. The winter stilling of the soil and the feeding of soybean hay or beans in the fall will help the horses to get their hair earlier and to be in better condition for spring work. By feeding the horses accustomed to some grain a short time before land work will help them to have more strength, more endurance, more flesh, and stand the winter better. E. T. Robbins, livestock extension specialist, College of Agriculture, University of Illinois.

Emerging Varieties for Planting in Fall-Fruit Growers

Now is the time for those who have an interest in small fruit growing to establish a plantation. Probably never before in horticultural history has there been such a number of high-class small fruit varieties available. For a number of years small fruit breeders have been at work, and their results are now becoming available. Especially hardy and vigorous and productive varieties bearing high-quality fruit and adapted to particular purposes may be secured and planted and, if given good cultural care, they yield both pleasure and profit.

Some of the new varieties of raspberries include: Alfred blueberry; Red Jewel current; Freedom blueberry; Fredonia (early black), Portland (early white), Sage (late-season red), and Sheridan (late black) raspberries; Chief, Latham, and Newburn red raspberries; Logan and Quillen blue raspberries; Fotsch purple raspberry; Blackmore, Dorset, Frontier and Easthill (fall-bearing) strawberries.

Several of these varieties are rather high in price at present because the supply of nursery stock is low. However, they may be purchased and propagated at home for an extensive planting. It is advisable to start with a few plantings, gradually increasing the acreage if soil and climatic conditions are found to be favorable and discriminating or at least profitable. H. J. Galloway, small fruit culture, College of Agriculture, University of Illinois.

## Hybrids Give New Advances in Production Of Corn

New possibilities for growing higher quality corn at cheaper costs through the use of hybrids are revealed in the latest bulletin just released by the experiment station of the College of Agriculture, University of Illinois. During the past five years the state's corn production had an average annual value of approximately 20 million dollars. Results similar to those reported in the bulletin open the way to the widening of the margin of net profit on the crop.

"Illinois Corn Experiments and Tests—Results for 1934," is the title of the new bulletin. The authors and the specialists who were in charge of the tests are E. H. Dungan, associate chief in charge of production at the college; J. R. Holbert, senior graduate in the Department of Agriculture, U. S. Dept. of Agriculture, associate in plant breeding at the college; T. H. Sargent, biologist, Illinois State Natural History Survey, and A. J. Sargent, assistant chief of the college's soil experiment fields.

Leading varieties of ordinary open-pollinated types of corn were far behind that of several hybrids in the tests. What was considered more important from the standpoint of future corn improvement was that the best commercial hybrids failed to compare with the better experimental hybrids.

For the first time in the official history of corn improvement efforts, the varieties of corn are tested and rated not on field alone but on the basis of four different factors entering into the "profitableness" of the crop. The four "yardsticks" are: (1) lodging resistance, (2) general quality of the grain, (3) total yield and (4) stunt grain. The average score on these four points was taken as the "performance rating" of the variety or variety.

Of the 122 different "kinds" of corn included in the 13 field tests in 12 different parts of the state, 45 were open-pollinated varieties and 132 were hybrids.

On the ten fields where comparisons were possible, the five best experimental hybrids had a "performance rating" of 26.5, the five best commercial hybrids 16 and the five best open-pollinated varieties a rating of 11.7.

The average yield of sound corn from the experimental hybrids was 46.3 bushels an acre, from the commercial hybrids 29 bushels and from the open-pollinated varieties 21.4 bushels. Many of the hybrids stood up outstandingly well against the test, drought and blanching of the 1934 season.

The search for corn of better quality--corn better suited to the uses to which it is to be put, whether for feeding on the farm or for commercial purposes--is expected to lead eventually to a more intensive study of the chemical composition both of grain and stover, the authors of the bulletin predict. The tests reported in the new publication are a part of the coordinated corn improvement program being conducted cooperatively by the College of Agriculture, University of Illinois, the U. S. Department of Agriculture and the Illinois State Natural History Survey.

Cats Loss Last Year In Winter Weather

About the quickest way for Illinois farmers to recover their cat crop losses of the past year will be to start this spring with improved and superior varieties, in the opinion of George H. Dungen, associate chief in crop production of the College of Agriculture, University of Illinois. The 1924 Illinois crop of 53,812,000 bushels was the smallest since 1874 and was valued at only \$18,412,000 as compared to a high of \$124,581,700 in a year like 1917.

Good quality seed cats will be scarce this spring, but whenever additional seed is bought, it will pay the farmer to select or secure selected and improved variety adapted to his locality, Dungen advised.

"Furthermore, with seed cats and many farmers having to lay their surplus, there will be a tendency to pay out, thereby to make the same outlay on each good variety. This will be hazardous in the case of the chance loss threat. The pests are much worse on thin crops than they are on thick ones. The danger of thin seeding may be avoided to a great extent by increasing the seed bed capacity and by using on fertile soil which will give more feeding to the plants. Seed loss can be saved by sowing with a drill. The bushels are saved with a drill as equivalent to three bushels sown broadcast.

"The best varieties for the different sections of the state are being singled out in tests which are being conducted at Urbana in northern Illinois, at Urbana in central Illinois and at Alton in southern Illinois.

"In northern Illinois Iowa, Columbia and Gopher are leading varieties. Columbia is an early, stiff-strawed cat, suitable for growing and seed crop. Iowa and Gopher are white cats suitable for home feed or for stock.

"Leading varieties in central Illinois are Columbia, Gopher, Burt (Nebraska 193) and Illinois 147. Burt is a red cat, early maturing, hard-strawed, but it is not as stiff-strawed as either Columbia or Gopher. Illinois 147 is a new variety developed as a selection from Sixty Day. There will be a small amount of seed of this cat for distribution to a few farmers early in the spring.

"Varieties of the type in Alabama include Franka, Columbia, Franklin, Burt (Nebraska 193) and Illinois 147. Franka is a red cat which was developed for dry-land conditions in Colorado. While it is a good yielding variety, it has heavy straw and for that reason may not be a better choice than the Columbia. Franklin is also a red cat. It is interesting that Columbia and Franka."

-M-

Lower Livestock In Check With Of Over-Stocking

With almost a fourth of livestock on Illinois farms to be sold this year, there will be a good season for farmers to break away from the evils of overstocking their pastures, says R. F. Sharp, associate chief in farm yields at the College of Agriculture, University of Illinois.

In the best corn belt farms have been getting off on the new pasture practice, he said. Even distinctly inferior farms the idea is to have one cow or horse for each 1 1/2 acres, while the new practice is to have one cow or horse for each 2 1/2 acres, he explained.

"At this rate of stocking, few farmers will have any surplus stock to sell to meet their needs. The solution is to get a few more cows or horses on the emergency pasture. Here again, however, overstocking will be a mistake."

-M-

Will Diseases of Corn Destroy This Year's Crops

Farmers are likely to catch on to any 1915 increase in the price of corn are getting ready now to protect their crops against threatened heavy damage by corn diseases, says Benjamin Foshler, associate chief in crop pathology at the College of Agriculture, University of Illinois. "Seed corn not only will be scarce this spring but also will be more expensive because of the rust diseases," he reported.

During the past crop season, annual yields of corn in the state's corn crop, was ranged from a high of \$4,400,000,000 to a low of \$2,400,000,000. This year corn diseases will play a more important role than ever before in determining the fate of the crop, Dr. Foshler said.

"Seed infections known as smut and fusarium were both unusually prevalent in the state last season. While these diseases cause rot and kernel discoloration, there are many infested seed corns which show no signs of infection until a germination test is made.

"Certainly when seed corn is planted this spring, it will be more important than ever to inspect the sowed grain from each ear to insure there are no discolored kernels. Remaining such grain will allow part of the disease to be taken.

"The best means of control will be to cull the seed ears already used and a germination test on every ear before planting those which show poor vigor or disease infection can be eliminated. In addition, the seed with good disinfectant especially prepared for this purpose. Farmers who are not equipped to make a germination test and do not wish to go to the expense of having it done will still meet it by carrying out the other two measures, that is, culling and seed treatment. These may be done at home.

"Corn seed infections do not damage in early-planted corn when germination is slow. For this reason, long-season corn should be planted in the first half of May in most parts of Illinois in order to make the best yields and the best quality of grain. If for some reason planting must be delayed until later, then seed treatment may or may not prove of value, depending upon the season."

-1-

Neglected Grape Vines Will Reap Careful Handling

The grape is believed to be the first fruit in history to be neglected and wasted, but nowadays neglect and inattention are running too often out of the possibilities of the crop in a state like Illinois, according to Dr. W. A. Selby, chief in state fruit culture at the College of Agriculture, University of Illinois. "This is the time of the year to start restoring this fruit to its rightful place here in Illinois."

Many long neglected or inproperly managed grape vines will respond satisfactorily to heavy pruning and may be made profitable producers if the stock which is healthy and vigorous and care is used in building the new crop. Dr. Selby pointed out.

"Grape seeds have been found with casides in Egyptian tombs of about 4,000 years old. Perhaps the long period over which the fruit has been cultivated and developed accounts for the fact it will respond favorably to proper pruning and training. Furthermore, the grape is so highly developed that it will show little growth and bear only a small crop of poor quality if neglected.

"Many neglected vines can be regenerated even though they are tangled masses of old canes, poor in soil with a heavy top and a few seedling canes.

## What Is to Be Done With the Pig in April?

Rising hog prices and the favorable market outlook have tempted the swine raisers to increase the number of pigs grown. It is to be held until 1 at the college of Agriculture, University of Illinois.

Unlike most other swine raising meetings, this one will feature the sow and litter phase of the hog raising. Instead of the finished pig, it is the fat market pig, according to Dr. W. D. Sherman, chief in swine husbandry.

Studies made by the college show that there is a wide variation in the cost of producing a pig to fat. The pigs are weaned three weeks after they are born. In their words, farmers seem to be more expert with pigs after they get them past the weaning stage than they are before that time.

Since the cost of raising a pig up to the weaning stage represents one-third of the total cost of raising him, the methods which the farmer follows in the early stage have an important bearing on his final returns.

At the time of the meeting, new facts on the feeding of sows and litters will be available from five different experiments which the college has conducted on this problem. Visitors will have an opportunity to inspect the pig pens first-hand at the college swine plant. Farmers will also have an opportunity to see hays and alfalfa pastured by means of a special arrangement. The pig, during a season, one and a half months. The methods of feeding and handling sows and litters in the farrowing pens will be exhibited. An improved type of farrowing crate also will be on display.

Following lunch, the speaker, Prof. H. F. Rusk, head of the animal husbandry department, will discuss the results of E. F. Corning, a member of the swine division, will report results of experiments on feeding sows during gestation, and Dr. Sherman will report results of experiments on feeding sows and litters.

The future of the pig market will be discussed by R. Ashby, associate chief in livestock marketing.

## Diseases and Insect Infestation of Tomatoes To Tomatoes

Now that the tomato has become the second most valuable crop and garden crop in Illinois, diseases and insect infestation are a danger to the heavier toll than ever before if they are not controlled. The most serious are brought out in a new circular just issued by the College of Agriculture, University of Illinois. It is entitled, "Tomato Diseases and Insect Pests: Identification and Control."

Disease-free seed, clean soil, soil sterilization, and crop rotation are important factors in keeping diseases out of the plot, and are discussed as general control measures.

Twelve of the most serious diseases are dealt with in the section on diseases prepared by H. J. Rowen, of the department of horticulture.

Control of nine different insects is explained by W. H. Shropshire, field entomologist for the Illinois State Natural History Survey.

Heavier Hatchings In Big Factor In Poultry Output

Future returns from Illinois poultry flocks will have to be figured on the prospect that there will be a big increase in the number of chickens hatched in the United States this spring compared with the number hatched a year ago. This is shown in reports which the College of Agriculture, University of Illinois has received from the U. S. Department of Agriculture.

The prospect of heavy hatchings is based on the January report from the big commercial hatcheries of the country. This January report is said to be a good guide as to what the hatchery and poultry industries are planning to do.

Thirty-three per cent more, or about a third more, baby chicks were hatched in January this year by 17 big commercial hatcheries than were hatched last year, according to the report. Hatchery hatchings in January were nearly 40 per cent higher than they were a year ago. At least some of the increased hatchings are the result of the fact that under the IRA act, hatcheries are now encouraging their buyers to place more of their orders in advance.

Increased hatchings are the result of several factors, according to the authorities. First there was the increasing egg prices in December, January and early February. Second, farmers now had the prospect of higher egg prices this spring than they had last year. In the third place heavy marketing both of young and old chickens as a result of last year's drought and later as a result of feed shortages reduced the number of chickens on farms to the lowest figure since the U. S. Department of Agriculture started keeping records 9 years ago. Farmers have started out to rebuild their flocks in the hope that feed supplies will be increasing here normal by next fall. That will be the time that early-hatched chicks will begin to lay.

111

Fewer Cows And Poor Pastures Help Hold Milk Prices

An estimated decrease of 3 to 4 per cent in the number of milk cows on farms coupled with the poor condition of many Illinois pastures this spring may shorten the annual spring drop in butterfat prices.

However, this annual decline in butterfat prices is only one of the spring worries of the cream producer. There are the lowering of cream tests, a decrease in the quality of cream and the presence of objectional flavors in the milk because of certain weeds which the cows eat, according to Dr. H. A. Ruehe, head of the dairy department at the College of Agriculture, University of Illinois.

Despite the danger to test in 1914, the return of spring pastures will bring an increased flow of milk and probably decrease in butterfat prices, he believes.

The quality of cream can be maintained in the spring to a large extent by careful handling, Dr. Ruehe believes. He emphasizes cooling the cream promptly to a temperature of 45 degrees Fahrenheit and marketing at least three times a week. By observing these and other precautions, dairymen will be able to market quality cream which will command good prices.

Wild onions, abundant in many Illinois pastures in the spring, impart an objectional flavor to cream, causing it to be graded down. The infested area should be fenced off or, in the case of bad infestation, the pasture should be abandoned until later in the spring when the onions have died.

Cream tests usually decrease in the spring owing to growth of pasture and weakening of cows. However, the increased volume of milk will usually more than compensate for the decreased test, Dr. Ruehe says.

112

Apple Moth Spreading Winter Cleanly Of Codling Moth

Whether or not the codling moth will do its annual toll of about a million dollars from the Illinois apple crop hangs largely on how thoroughly growers wind up the winter cleanup of this pest. This is the opinion of two different authorities, S. C. Shandler, field entomologist of the Illinois State Natural History Survey, and V. W. Kellogg, horticultural extension specialist of the College of Agriculture, University of Illinois.

So serious was the pest in 1923 that it estimated one-tenth of all the apples produced in the state were infested with codling moth worms. The average annual value of the state's apple crop has been about a million dollars, and one of the most costly limits to this value has been the codling moth.

A thorough winter cleanup is one of the most telling ways of combatting the pest, the authorities pointed out. At the present time the insects are in the overwintering cocoon stage. Each cocoon of the overwintering first winter generation produces 70 eggs which yield 1,000 worms of the second brood and 10,000 of the third brood. This would be enough to eat a 100 barrels of apples. If the attention upon the pest is delayed until the end of the second brood, the destruction of a pair of moths at that stage means preventing only one pair worms to infect about one year of apples.

Cleanup work should start in the cleaning shed, especially if the snows melt and winter variations. If it is desirable the entire shed should be screened and kept closed until the moths have emerged and died. One grower was screened his shed with brown cotton cotton prevented the escape of 50,000 moths into his orchard at a cost of only \$21 a year.

If screening is impracticable, the next best thing is to place all orchard crates and old used baskets and equipment in a closed room which is moth-tight. Crates and baskets can be dipped in a mixture of boiling water until the worms are exterminated.

In the orchard itself the trees should be covered during the winter preparatory to putting on the codling moth bait during the following summer. The rough bark which is scraped off should be burned. Pruning out any dead, split branch ends and partially rotted knots deprives the codling moth in one of its favorite hiding places. Burning the prunings is important. Pruning so as to open up the centers of the trees will make it possible to cut the codling moth's way into the inner branches.

From 75 to 90 per cent of the worms in an orchard are found in or on various objects on the ground under the trees. Consequently the cleanup is not complete until every piece of old basket crate, fertilizer sack and all other trash is burned.

Chick Raising In Mystery But It May Prove Expensive

Raising baby chicks, the latest innovation in modern poultry raising, is no longer a fad or a mystery, but it may be of limited value to the general run of farm flock owners, according to H. H. Ahl, poultry extension specialist of the College of Agriculture, University of Illinois. Interest in the question is at the peak now with the baby chick season at its height, he pointed out.

Raising sexed chicks so as to get only pullets and no cockerels may be justified in certain instances, Ahl said. On the other hand the flock owner should weigh the increased initial cost of the chicks, the heavier losses from mortality as a result of the higher cost of the chicks and the loss of income from the sale of cockerels.

## Trade Can't Be the Answer to Unemployment

Trade restrictions are not the answer to existing international trade and restoring to the world the economic balance which little if any threat to the welfare of wage earners. The fact, which relates the close economic ties in many quarters, is borne out by the fact that the College of Agriculture, University of Illinois, from the Agricultural Experiment Station.

Frederick L. Stutz, president of the Illinois State Board of Trade, is held to be a barrier to the revival of foreign trade with the result of a loss of business to foreign countries to trade their goods for U. S. products.

Stutz, however, is more concerned in this country, and a small part of the country's production is protected by the tariff, it is shown in the report. In 1936, for example, the country employed 5 million unemployable workers. More than half of the country's production is in non-manufacturing industries with which imports can not and do not compete. These, however, are engaged in such industries as internal transportation, electrical, building, insurance, building, public service, and so on.

Of the 5 million unemployable workers, 2 million were employed in industries for which the tariff is not a protection. The most important group was employed in manufacturing which could not be protected by imports. These included such domestic industries as printing and publishing, and other industries which produce materials which are protected against foreign countries by tariff and other industries which produce mass production in which foreign competition can not undersell the efficient American producer.

It is estimated that at most 1 million American wage earners in six is competing directly with foreign wage earners. In making tariff adjustments the problem of what is to be done if the workers whose industry depends to some extent on tariff protection are not to be considered.

On the other hand, will some industries which contract their production if tariff reductions are permitted expand in international trade, others would expand under the new conditions. Jobs in these industries would consequently become available.

## Vocational Association Plans April Meet At U. of I.

Approximately 150 delegates from 15 states are expected to have 1,000 delegates and representatives at the University of Illinois for the annual spring convention of the Illinois Vocational Association on April 19 and 20. It is announced by Prof. A. B. Gys, a member of the association board of directors and professor of industrial education at the university.

Marking a new advance in the field of vocational education, the convention, for the first time, will bring together the Illinois Association of Vocational Agriculture, the Illinois Industrial Education Association. The new set-up will include the Illinois Vocational Association. Vocational education interests represented in the meeting will include, but not be limited to, agriculture, trade and industrial education, part-time education, home economics and guidance.

Pasture Holdings Fut. Of Illinois Dairy Returns

Few things will have as much bearing on the returns from Illinois' 1,178,000 dairy cows this season as the solution of the pasture problem resulting from last summer's hot, dry weather, says Prof. C. S. Rhoads, of the Dairy Department, College of Agriculture, University of Illinois.

There are at least three mixtures that are suitable for replanting permanent or rotation pastures, he said. Mixture No. 1 contains 4 pounds of bluegrass, 4 pounds of orchard or bromegrass, 3 pounds of timothy, 1 pound of reitop and 2 pounds each of alsike, red, sweet and white clover. Mixture No. 2 is the same with the exception that no reitop is used, the timothy is reduced to 2 pounds and 3 pounds of lespedeza are included.

A third mixture contains 5 pounds of red clover, 3 pounds of sweet clover, 2 pounds of alsike and 4 pounds of timothy. Amounts included in each mixture are sufficient to seed one acre of land. If the soil is acid, sweet clover should not be used in any of the above mixtures.

These mixtures may be seeded early in the spring along with two bushels of oats to the acre. The oats serve as a nurse crop and also furnish some of the winter pasture. The ground should be disced before and after the seed is planted. The grain seed is sown after the ground has been raked with a corrugated roller. The rolling operation should be repeated after seeding has been completed.

Oats also may be sown with a larger mixture. The bushels of oats to one and one-half bushels of Cornish field peas make a good winter pasture after the early oats are gone.

Another good emergency pasture mixture is 2 bushels of oats and eight pounds of sweet clover or alfalfa or a legume mixture including red and white clover. The pasture during the hot, dry season, 1 pound of timothy grass and 1 1/2 bushels of sorghum are usually satisfied crops. This mixture should not be sown until after corn-planting time and may even be delayed in the middle of the summer.

-16-

Slump In Exports Shows Likelihood Of Increasing Output

Steps which Illinois farmers are taking to adjust their production program more sound than ever in view of the further slump in farm exports from the United States. The most recent available figures show, for instance, that in January the smallest volume of farm products in more than 29 years was shipped out of the United States, according to a report just received by the College of Agriculture, University of Illinois from the U. S. Bureau of Agricultural Economics. The January, 1935, index for farm exports was 57 as compared with 62 in December and with 93 in January of 1930.

All products except fruits were exported in less than pre-war volume in January. The index figure, as compared with 100 for pre-war, were: grains and products 17, animal products 33, dairy products and eggs 19, fruit 189, wheat and flour 14, tobacco 97, hams and bacon 18 and lard 45.

Exports of wheat and flour, including flour milled from Canadian wheat, were 1,310,000 bushels in January, one of the smallest monthly exports on record. Total exports of wheat and flour from July 1 to January 31 were 14,450,000 bushels compared with 18,607,000 bushels during the corresponding period of 1934-35.

Index of cotton exports in January was 68 compared with 109 in January last year. Exports this January were 486,000 bales against 783,000 bales a year ago. Total exports for seven months ended January 31 were 3,375,000 bales compared with 5,419,000 bales during the corresponding period of 1934-35.

Hamlets, and neglected for 25 years. In 1890, small fruit growing is now giving its life, according to Dr. A. S. Cobb, and is being cultivated at the College of Agriculture, University of Illinois. The time has come for those who have an interest in such crops to get bluish plant to grow, and so on.

One thing which has stimulated interest in small fruit growing and has opened the new day for such crops is the present trend toward lightening and increasing production, Dr. Cobb says. That is, both in quantity and in quality. Fruit are expanding rapidly. Hazards from insects and diseases are being overcome through research. Probably never before in history has there been such a number of high class small fruit varieties available as there are now.

Exceptionally hardy, vigorous and productive varieties now available include: Alfred blackberry; Red Lake currant; Freedom gooseberry; Freedom (early black), Portland (early white), Cico (mid-season red) and Sheridan (late black) grapes; Chief, Idaho and Newburgh red Logan and Gillenblom raspberries; F. T. people raspberry; and Blackmore, Dorsett, F. T. and Rockhill strawberries.

Several of the varieties are of an early bearing because of low supplies of fruit stock. However, they might be purchased and be propagated at home.

Best results will be obtained if the varieties selected are suited to the soil and climate particular to the locality. It is always best to start with a small acreage and site suitable to the needs of small fruit growing.

The plants require the best of attention and care and should be sprayed if necessary to maintain their vigor and high-yielding qualities. When fruit is to be sold on the market, it must be picked and graded properly and placed in clean packages of the size and style demanded by the trade. It should be moved rapidly and carefully to market.

Small farms can still be connected with business, and produce garden and vegetable crop.

707

Farmers War On Rats. "Black Mouse" "Muscle" "Rat"

Rats are a public enemy No. 1 and it is for that reason of the season for they not only kill thousands of baby chicks, but also destroy feed and other property, according to G. C. Odierman, of the U. S. Biological Survey. He is cooperating on rodent control in this state with the State Natural History Survey and the College of Agriculture, University of Illinois.

Food and red spill is the best bait for fighting rats, since it is readily taken but comparatively harmless to domestic animals and humans. The spill should be mixed with corn bait such as canned salmon, hamburger or a mixture of moistened rolled oats and corn. One part of poison to 10 parts bait by weight is the correct proportion. The different baits should be put out in teaspoonful quantities so that the rats may enjoy their preference.

Even though red spill is comparatively harmless to domestic animals, care should be taken to prevent chickens, cats or dogs from eating large quantities of the poisoned bait.

Calcium cyanide fumigant is another rat exterminator which may be used successfully, especially in burrows, under concrete floors and other places where the gas can be confined. It should be applied with a foot pump. Water is used for the purpose. The operator should avoid breathing the poisonous fumes.

Other steps which will help rid the premises of rats include burning of rubbish and piling lumber and boxes so that there is no space underneath. Co-operative community rat campaigns during which poison is distributed all over the community at the same time are also effective.

## Illinois Soil Conservation Program Approved

Conservation of soil and water resources is one of the most important problems confronting the farmer today. The Illinois Soil Conservation Program, which is being developed and supported by the Federal Government, is designed to help the farmer solve these problems.

A comprehensive conservation program has been set up to help the farmer solve these problems. The program is being carried out in cooperation with the Federal Government. The Illinois Soil Conservation Program is being developed and supported by the Federal Government. The program is designed to help the farmer solve these problems. The Illinois Soil Conservation Program is being developed and supported by the Federal Government. The program is designed to help the farmer solve these problems.

The first of the major objectives of the program is the conservation of soil. This is being done by the establishment of soil conservation districts. These districts are being established in cooperation with the Federal Government. The Illinois Soil Conservation Program is being developed and supported by the Federal Government. The program is designed to help the farmer solve these problems.

A special committee of the Board of Agriculture has been appointed to study the problem of soil conservation. The committee is being headed by the Director of the Board of Agriculture. The Illinois Soil Conservation Program is being developed and supported by the Federal Government. The program is designed to help the farmer solve these problems.

Farmers May Lose Selling Their Stock To Speculators

Rising livestock prices have sent a swarm of special time buyers into the country, it is reported by E. T. Robbins, livestock extension specialist of the College of Agriculture, University of Illinois. Farmers run the risk of losing much of the benefits of the price boom if they sell to these buyers instead of consigning their stock themselves to the central markets, he said.

"Farmers have nothing to fear from honest, legitimate buyers, but in times like these it is more important than ever that producers be sure of their ground before making a deal on their stock. Only by visiting a market frequently and noting the quality of cattle and the kind of prices they bring can any farmer realize the changes which have taken place. Many grades of cattle are twice as high as they were a year ago.

"Speculative buyers now swarming the country may quote a price which looks attractive to the farmer but which may still keep him out of an additional return that he might get by selling some other way. Farmers have even been called out of bed in the eagerness of buyers to offer them practically as much for their stock as it would bring on that day's market. The activity also has extended to the buying of hogs, which have advanced considerably since the first of the year."

Although the market does not always operate to make this possible, the farmer, shipping his own stock to the central market, stands the same chance of making a profit as does the speculative buyer, it was pointed out.

"In the long run farmers probably get the most money for their stock when they consign it to the central markets or have their local cooperative marketing associations do it for them. At these central markets the animals sell strictly upon their merits at prices set by competitive bidding. It is not necessary for the farmer to be fully informed upon the last day's values in order to sell his stock as high as it can be sold. The commission men take care of that."

New Standards In Apple Cooling Set By 1. Tests

New standards for the refrigeration of apple shipments have been set up as a result of further experiments by the College of Agriculture, University of Illinois to reduce present heavy losses in fruit marketing. Reports of the latest studies are given in a new bulletin just issued by the experiment station of the college under the title, "Factors Influencing the Refrigeration of Packages of Apples," by J. W. Lloyd, chief in fruit and vegetable marketing, and S. W. Decker, associate.

Findings made in the study have an important bearing on the marketing of the Illinois commercial crop, which amounts to nearly 60 per cent of the state's total estimated crop of 5,000,000 bushels.

The experiments were carried out with special apparatus which the investigators constructed to produce conditions similar to those found in refrigerator cars.

Use of the lined tub basket, basket hamper or ventilated corrugated basket box as an apple container allowed fairly rapid cooling of the fruit to the desired 45 degrees Fahrenheit. Unventilated corrugated boxes or the lined western apple box retarded cooling, as did also the use of oil wraps around the individual apples.

In addition to this information regarding the relationship of the package to rate of cooling, the experiments showed that size of the fruit had little to do with the rate of cooling but that the velocity of the air was an important factor when it got above 100 feet a minute. Pre-cooling was shown to have a decided influence in preventing spoilage.

-M-

Beef Consumers Can Blame Woes On Ravages Of Drouth

Increasing complaints about the price of beefsteak going up while the quality is going down are just another result of the 1936 drouth and neither the farmer, the packer, nor the butcher can be blamed, according to the College of Agriculture, University of Illinois.

Fortunately, there is still plenty of nutritious beef to be had, provided consumers know what to look for, it is pointed out by Prof. Sletcher Bull, associate chief in meats. The housewife can still get her money's worth if she will put a little added skill into her selections of beef, he said.

"Prices of beef have been forced up by the drouth because short feed and water supplies compelled farmers to sacrifice livestock as quickly as possible with the result that today there are fewer cattle to go to market. At the same time the general quality of beef has been temporarily lowered as an aftermath of the drouth because underfed cattle yield meat that is less fat and tender.

"Consumers in some markets may be able to get beef that is graded for quality and if so, these grades will assist them in making a more satisfactory selection of meat. For all consumers, however, there are a number of tips which will enable them to do their own grading when they go to the butcher shop or meat market.

"In looking for 'prime' beef, consumers are likely to find that it is very scarce, even when fat animals are plentiful. The color of the lean in such beef ranges from bright pink to bright cherry red with thin white lines of fat called marbling running through it like vines. The meat is covered with a thick, even layer of firm, white fat. Cut surfaces are smooth and firm.

"'Choice' beef has about the same characteristics as 'prime,' but is not so fat. 'Good' is considerably above the average and good enough for most people in the best of times. 'Medium' and 'common' are not so well flushed, the lean is a darker color with no marbling and the fat is thin and yellow. Such meat usually comes from older cattle of dairy or scrub breeding. However, it is quite nutritious and if properly cooked is also palatable.

"Color and marbling are the essential items for the amateur grader to remember. The lean should be bright cherry red with at least some marbling running through it. The fat should be white or creamy white."

-14-

Sound Program Now Needed In "Boon" Of Small Fruits

With small fruits staging a come-back in Illinois, a sound program of variety selection, planting and culture is needed to head off disappointments which would come from that "wild" rush of farmers into the small fruit field, according to a new circular just issued by the College of Agriculture, University of Illinois. Entitled, "Bramble Fruits," the new circular outlines new and improved methods of growing raspberries, blackberries and dewberries in Illinois.

Cultural practices are dealt with in a section by Dr. A. S. Colby, chief in small fruit culture; bramble diseases and their control in a second section by Dr. H. W. Anderson, pathologist in the pathology division, and insect and their control in a third section by W. F. Flint, chief entomologist of the college and of the State Natural History Survey.

The value of sanitary measures in the culture of brambles is stressed in the circular, and a recommended spray schedule is included.

### Good Oils Would Add 140,000 Years to Tractor Life

As much as 140,000 years and possibly 210,000 years of service might be added to the 70,000 farm tractors in Illinois through proper crank case oiling and maintenance, says R. I. Shawl, of the department of agricultural engineering, College of Agriculture, University of Illinois. Seven years is the average life of a tractor, while machines given proper care are still in service after nine or ten years, he said.

Importance of using proper crank case oil in prolonging tractor life has been brought out in studies which the college has been conducting since 1928. A cardinal principle established in these tests is to pick the lightest grade oil of the highest quality that can be used without increasing oil consumption or crank case dilution. Such an oil, it was found, will be the cheapest, will last longest, cut down repair bills and, in addition, prolong the life of the tractor.

Three samples of heavy oil have shown excellent resistance to heat and crank case dilution. However, these oils have proved too heavy to give proper lubrication except when the pistons and cylinders were badly worn. Making repairs is more satisfactory than the use of extremely heavy oils when the motor becomes worn, Shawl believes.

Two samples of light oil showed good lubricating qualities, but were too light to prevent dilution and excessive oil consumption. A slightly heavier grade gave much better results.

Cheap oils used in the tests proved unsatisfactory. They did not give proper protection to working parts nor did they resist heat and dilution. Some of the cheap oils thinned out under excessive heat, while others thickened to the extent that they could not reach to points of friction.

-4-

### Seed-Type Soybeans Are Best Bet For Record Acreage

Record plantings of 1,632,000 acres of soybeans which are indicated for Illinois this year are likely to yield farmers the best harvest of hay or of beans if they are made with the varieties that ordinarily are thought of as grain producing types, according to W. I. Burlison, head of the department of agronomy, College of Agriculture, University of Illinois.

Experiments which he and his associates, J. C. Hackleman and C. A. Van Doren, have conducted for five years show that the grain producing types of soybeans also have superior hay producing qualities. The grain, or seed, types averaged 3.41 tons of hay to the acre as compared to 3.07 tons for the hay varieties.

Where several late-maturing hay type soybeans are being compared with seed type varieties, the latter have continued to outyield the hay types for hay as well as for seed.

While the seed types may not produce more forage than the hay types in all sections of Illinois, crops specialists believe the dual purpose qualities of the seed types may make them worthy of consideration.

The seed types used in the five-year tests were: Dunfield, Hancock, Marcha and Illini. The hay types were: Kinga, Peking, Ebony, Wilson V and Virginia.

Farmers who intend to plant either to seed or hay type varieties this spring should get their seed supplies as soon as possible, Burlison said. About half of the 1934 soybean crop of Illinois was sold by December 1, 1934, leaving approximately 5,000,000 bushels in the hands of growers.

At least 2,000,000 bushels will be required to plant the anticipated 1935 acreage in this state. Increased seed demands from states where the South has reduced seed supplies would indicate that soybean seed may be scarce later in the season.

-4-

Gains In Control Of Fruit Diseases Gained By Spraying

Advantages gained by Illinois fruit growers in 1916 through the destruction of insect pests and diseases may be fully appreciated this year by proper spraying, says the College of Agriculture, University of Illinois. Leafhoppers and other insects are controlled in a new circular, No. 409, which the college has just issued under the title, "Directions for Spraying Fruits in Illinois." It was prepared by F. W. Anderson, chief in fruit diseases, and W. D. Flint, chief entomologist of the Illinois State Federal History Service and of the Agricultural College.

Fruit growers should fruit early in spring the coming season and use the importance of spraying to prevent the potential losses, the circular points out.

Last year some apple growers followed the recommended schedule for reduced budling with infection in their crop from 50 per cent in late August to 80 per cent in 1916. Insects and diseases attacking other fruits were similarly controlled when orchard sprays were applied. While it is too late for the dormant sprays, the later applications will do much to maintain the control gained last year, Anderson and Flint believe.

"Public enemies" of the fruit grower and the fruit consumer are which common measures are outlined in the circular include: fire blight, San Jose scale, cherry curculio, cherry scale, water shell scale, cankers, fungous diseases of apples, leaf spots, pear scab, rusty blight of apples, brown rot, bacterial rot, blights, leaf scald, anthracnose, red cedar scale and other diseases and insects that occur on fruit and plants.

Spraying schedules are included for apples, peaches, plums, cherries, plums and the various small fruits grown in Illinois.

There is also a complete section on the preparation and use of oil emulsion, Bordeaux, lime sulphur and lime sulphur soap. General directions for spraying as well as precautions to be observed are included.

-11-

Improved Poultry Houses Will Help Fortify Profits

Any profits resulting from better poultry and egg prices may be more certain if good hen houses are provided, in the opinion of E. A. Foster, rural architect in the College of Agriculture, University of Illinois. This spring, when raising and building projects are being pushed, is a good time to start getting the buildings in shape for the fall and winter season, he believes.

To assist Illinois farmers and poultrymen in building better houses, the college has assembled some 20 blue-printed plans for poultry houses and equipment. These plans are supplemented by college circulars No. 410 giving directions for construction of the straw-loft house, and No. 413 with instructions on building the shed-roof type. These plans are also included in the blue prints available.

All of the plans are based on observations made by Foster in cooperation with the poultry husbandry division. They include information on the construction of houses, feeding equipment, water apparatus, laying boxes, and brooding houses and equipment.

Reduced farm incomes during the past few years have caused many poultrymen to neglect making repairs on their buildings and equipment. This has added to the demand for information on repairs and alterations. The popularity of poultry as a means of adding to the income of low-paid workers and subsistence families has also created a demand for cheap but satisfactory poultry equipment built, if possible, from good lumber.

## 4-H Club Girls Will Keep For a Year or More

Many of the worries about "it is just a passing fad" and what is going to happen to it can be quieted by directing the attention of some of the 47 Illinois farm and small town girls enrolled in 4-H club training, says Mrs. A. McKee, former club specialist of the College of Agriculture, University of Illinois.

The 4-H training has not diminished and it has not lowered the morale of the girls, she reports. This spring many of them are going to be abroad with a new zest and enthusiasm, she added. While many of the club members were on spring training last year, the spring also marks the forming of new clubs, the carrying on of new members and the starting of new projects.

As an illustration of what has been accomplished last year, she says, during this year, they made more than 100 projects in 4-H. In addition, they made 170 garments and 1000 pairs of shoes.

Activities of club girls are not limited to making work. They have a complete course of 14, 16 meals each last year, including the food, service to meals, washing the dishes and cleaning the kitchen after each meal. In spite of a dry summer, they canned and preserved, and made 100 projects for it and 100 articles of 100. They brewed and made 1000 lbs. of butter, 100 lbs. of soap.

Many of the girls also have been in the classification of 4-H club projects. Approximately 1000 articles of the home furnishing type were made by club girls of the state last year. They added to the comfort, beauty and serviceability of 100 homes through their efforts.

All club work is done in the neighborhood and they have a definite responsibility and where their responsibilities are subjected to the strict test of being practically applied at the point of every day use.

Girls who wish to enroll in clubs this year or start clubs in their communities, should get their names or farm advisers, Mrs. McKee says.

-16-

## W. A. Brock Succeeded To W. A. Harrington in LaSalle

W. A. Harrington, formerly farm adviser in LaSalle county, and C. H. Best, farm adviser in DeWitt county, figure in the two most recent changes in the ranks of Illinois farm advisers, it is announced by Prof. L. C. Wither, head of the department of farm advisers at the College of Agriculture, University of Illinois.

Mr. Harrington resigned April 1 to accept a position as inspector in the farm bureau farm management service of the department of agricultural economics. Mr. Brock will succeed Mr. Harrington and will take up his new duties in DeWitt county on May 1.

-17-

Further Delay In Getting Soy Seed Will Be No Fudge

Farmers intending to plant soybeans this spring will do well to obtain their seed supplier before the last minute, in the opinion of W. C. Hackleman, crop production specialist at the College of Agriculture, University of Illinois. An estimated 11 per cent increase in the national soybean acreage indicates that there may be a seed shortage, he said.

Factors pointing toward increased soybean acreage are: Danger of chinch bug infestation; new land available for soybean planting through provisions of 1954 soybean contracts; favorable seed prices; the need for legume hay; increased capacity of processing plants; and increased acre for soybeans.

In addition, it is expected that seed demand from the South will be strong.

With millions of chinch bugs coming out of winter quarters, many Illinois farmers will find soybeans valuable this spring because of their bug-proof qualities. Then too, Hackleman explains, last summer's demand for hay and pasture has increased the need for legume hay which may be grown on land taken out of corn production.

The chances are, he says, that soybean seed prices may be somewhat lower than during the January and February years, but they will still be high enough to afford the grower a profit. Additional processing plants were built in 1953 and more are planned for this year. These plants are needed to take care of the demand arising from soybean drinks, breakfast foods, macaroni, noodles, ice cream and dozens of other new products made from this crop.

-41-

Record Planting Rate Expected On Soybean Inoculation

With Illinois farmers preparing to plant soybeans here for this spring, L. E. Allison, Assistant in soil biology at the College of Agriculture, University of Illinois, points out that inoculating the seed bed with nitrogen-fixing bacteria is one of the two or three main essentials for success with the crop. Good inoculants bought from a reliable firm will be cheap and insurance for soybean growers this year, as in every other year, Allison said.

Nitrogen is necessary for the satisfactory growth of soybeans. The chief available source is the free nitrogen in the air, but it must be fixed by the bacteria before it can be used by the plants. Acid soils or those on which legumes have not been grown for some time are usually void of the needed bacteria, and, consequently, produce very poor soybeans unless inoculated.

The best inoculation method, Allison says, is that of adding the bacteria to the seed just previous to planting. Through this method, the bacteria cling to the seed and concentrate the roots as soon as the seed germinates. Inside the roots they form nodules which are soon filled with more nitrogen-fixing bacteria.

A plentiful supply of nitrogen is essential to high yields of soybeans as well as to high protein content of the beans. The food value of both the hay and beans is increased by high protein content.

Another important point stressed by Allison is that plants supplied with plenty of nitrogen are better equipped to withstand dry weather.

Commercial legume inoculants may be purchased in two types, the dry culture or jelly type sold in bottles, and the type having either a slurry or soil base.

-41-

Chickens Die Due Cold In Indianapolis Poultry Plants

Farmers and poultrymen were suffering big losses this winter from the cold and thereby sacrificing future gains and were to a likely extent liable to influenza, disease, or bacillary white diarrhea, according to a circular from the United States issued by the College of Agriculture, University of Illinois. This year, when market prices are rising and the outlook for the industry is generally favorable, the prospect of a more costly winter than ever, it was pointed out. Dr. Robert Graham, chief in animal pathology and hygiene, is author of the new circular.

First of ten practices which he outlines for the flock owner's defense against the disease is to avoid buying or carrying diseased or infected flocks. The disease is one of the few affecting poultry which can be transmitted directly through the eggs to the chick.

Other safeguards in the first heading defined set up by Dr. Graham are: (1) Disinfect incubators, hatching boxes and equipment; (2) Do not take eggs from tested and non-tested birds in the same incubator; (3) Carry eggs in a separate box; (4) Use clean grass mats which have not been soiled by dirty flocks; (5) Do not mix up the old ground frequently; (6) Do not feed old feed which may contain material resistant to disease.

(7) Avoid feeding feed until, and on the day of, hatching all feed bins by burnings; (8) Test eggs up to 48 hours before hatching and separate from the diseased and test infected flocks until all are reproduced; (9) Grow birds raised all recovery; and (10) Test all stock before and for the first time and disinfect once a month or as often as necessary to hold the disease in check.

11

Fowl Pox Linked As Cause In A Large Poultry Plant

No matter how high poultry prices may be, it is doubtful if the new crop of layers which farmers are now obtaining will be as profitable if fowl pox gains a foothold, according to a new circular on the disease just issued by the College of Agriculture, University of Illinois. Designed to help growers by isolating flocks from the disease, the circular was prepared by Dr. Robert Graham, chief in the animal pathology and hygiene division, and Dr. T. W. Sawyer, assigned to that division from the state department of agriculture.

Outbreaks of fowl pox, if promptly diagnosed, may be suppressed by proper cleaning and disinfection of the premises and by destruction of all infected birds. If a large number of birds are infected, destruction is not so practical a measure as sanitation coupled with vaccination, according to the circular.

All birds in the flock should be vaccinated if symptoms of the disease are detected or if there is danger of fowl pox being introduced into the flock. Either fowl-pox or pigeon-pox vaccine may be used, but pigeon-pox vaccine is less effective according to the circular. Its use is best limited to cases where a severe reaction may cut egg production or injure young birds. Methods of vaccinating are given in the publication. Immunity to the disease lasts for six months to the life of the bird.

The best time for vaccinating flocks on infected premises is in the winter, at least two months before the birds begin to lay. Birds that are to be vaccinated should be given sufficient time to recover completely from the effects of the disease and treatment before entering production.

## Infertile Seed Is Barrier To Growth of Corn Crop

Elements of the Illinois corn crop are being undermined by the fact that a considerable amount of infertile seed is being offered for sale at comparatively low prices. According to Dr. H. C. Harkness, an extension specialist of the College of Agriculture, University of Illinois.

As a general rule, farmers are content to get by buying seed which will be lost many times over through soil infertile and low quality seed, but in 1914.

For several years past the standard has been set by the small corn crop that has been secured from the seed of the 1913 crop. The Illinois average of corn yield in 1913 was 77.2 bushels per acre, and in 1914 it was 70.5 bushels per acre. The crop in 1914 is being held back by the fact that the quality of the seed produced in 1913 was only four bushels per acre less than that of the 1912 crop.

The reason for this is that the seed of the 1913 crop was of an uncertain quality. The reason was made in the fact that the bureau and management service agencies in Mexico, Livingston, the seed of the 1913 crop.

Tests conducted by the agricultural college in the state of Illinois from 1912 to 1914 indicate that an annual average of seed loss of \$11.00 per acre from over-planting and under-planting of seed of the 1913 crop was a poor seed crop was 1913 and the crop was saved for 1914. The average loss of \$11.00 per acre was avoided.

While it is true that the cost of the high-quality seed corn in the state, Harkness said.

The late lists of quality seed corn available in Illinois this spring can be found in the office of the Agricultural Extension Service, University of Illinois, Urbana, Illinois, as the factor which will determine the quality of the seed.

-1-

## Dr. H. C. Harkness, Jr., Is Illinois Man

Dr. H. C. Harkness, Jr., was a graduate of the College of Agriculture, University of Illinois. He has been brought into the service with the recent appointment of Dr. H. G. Black, chief of the Bureau of Agricultural Economics, U. S. Department of Agriculture. He succeeds H. A. Black who resigned April 15.

Dr. Black was born in Florida on April 15, 1887, the son of Mr. and Mrs. Hudson H. Black. He was graduated from the U. S. College of Agriculture in 1911. Shortly after his graduation from the University of Illinois, Dr. Black was employed as agricultural economist for the Federal Farm Loan Bureau at Washington, D. C. He remained at Washington until 1912 when he became associated with the First National Bank of Dallas, D. C. It was in 1914 that he left this position to become assistant professor of agricultural economics at the University of Minnesota. From 1914 to 1919, Dr. Black taught at Minnesota and did graduate study. In 1919, he became chief of the department of agricultural economics at Iowa State College. He was a member of Washington, D. C. in 1912, 1913, to serve as chief of the 1914 corn-crop survey. On February 5, 1914, he was elected in charge of the live-stock work, including the following committee, etc., and etc.

3 Million Less Acres Needed For Corn In This Plan

Three million fewer acres would be required to produce Illinois' average annual corn crop if all farmers used limestone and either barnyard manure or green manure in a good rotation, including clover, according to L. B. Miller, associate in soil experiment fields at the College of Agriculture, University of Illinois.

Such a change would cause a direct saving of many millions of dollars each year in production costs. It also would greatly reduce the annual losses from erosion and leaching and in the end would prolong the life of corn belt soils for future generations, he pointed out.

The estimate that the total size of Illinois corn fields could be reduced by three million acres is based on ten-year average results from 24 soil experiment fields which the agricultural college maintains in different parts of the state. Corn yields on these fields were improved 15 to 18 bushels an acre by the use of limestone and either barnyard manure or green manure in a crop rotation system including clover.

In contrast to these results, mineral fertilizers have improved corn yields only 2.4 bushels an acre. This is the average for 45 trials which the college made in farmers' fields under many different soil conditions. There were a few special soil conditions where mineral treatment was profitable, owing to potash deficiencies, but in the more normal soils the response from mineral fertilizers usually was not enough to justify the expense and the trouble.

Interest in fertilizing the corn crop to get the most efficient and the most profitable yields is reviving this year because of the higher corn prices, Miller pointed out. If money is to be spent for this year use it is best spent for limestone and for seeding soil improving legumes, he recommended. Corn needs a soil high in organic matter, and this can not be bought in a fertilizer sack. It can, however, be produced on the farm as barnyard manure or as crop residues and green manure.

The average annual yield of Illinois' nine million acres of corn has been approximately 31 bushels an acre with little variation during the past 40 years. The benefits of new varieties and better cultural methods have just about balanced the increasing damage done by plant diseases, insects and soil depletion.

-M-

Old Clover May Make Profitable Seed Crop This Spring

With a 10-million-pound shortage of red clover seed supplies in prospect this year, Illinois farmers may be able to reap extra cash by saving any three-year-old red or mammoth clover fields which they have, it is pointed out by J. J. Fieper, associate chief in crop production at the College of Agriculture, University of Illinois.

Although it is not generally known, either red or mammoth clover that was planted in 1933 is capable of producing hay and seed this coming summer if there is still a good stand of the crop, Fieper says. Red and mammoth clover are both perennials, but are usually killed out by the clover root borer during their second year.

This borer destroys many of the roots and weakens the plants to the extent that they usually winter kill during the second winter. For some unknown reason, the root borers have not been effective in Illinois recently. Consequently, there are many three-year old fields of red and Mammoth clover in good condition this spring.

These fields, under normal conditions, should produce one good hay crop and a good seed crop this coming summer, Fieper believes.

The national average production is 40,000,000 pounds annually, with 1934 production down to 30,000,000. This amount plus 14,000,000 pounds carryover is still 20,000,000 pounds short of the average annual consumption.

-M-

Poisonous Weeds Worse Threat To Stock This Spring

Danger of livestock losses from poisonous plants has been heightened in Illinois this spring by short pastures and the lack of feed with which to finish the winter season, it is reported by Dr. Robert Graham, chief in animal pathology and hygiene at the College of Agriculture, University of Illinois.

Requests for information on the treatment of farm animals poisoned by whorled milkweed and other poisonous plants have already started coming to the college. With winter feed supplies lower than usual, he expects early grazing to result in a greater than usual number of horses and cattle being poisoned this year.

Quite often the farmer is not aware of the danger until he finds some of his animals dead, Dr. Graham said. This is especially true where poisoning has resulted from the first growth of cockle burrs. This weed is highly toxic in the early stages of its growth and works rapidly. However, cockle burrs do not appear until later in the spring.

In many cases, the farmer may notice such symptoms as weakness, paralysis, abnormal alertness, rapid loss of weight or a tendency to stumble and fall. As soon as such symptoms are noticed, a graduate veterinarian should be called to administer stimulants and purgatives. With the slower acting poisons, prompt treatment by the veterinarian may often result in a cure.

The best measure is to keep poisonous plants out of reach of the stock, says Dr. Graham.

Ripened seed pods of the so-called coffee bean tree, as well as pods from black locust trees cause considerable poisoning in the spring, according to J. J. Pieper, associate chief in crop and animal husbandry at the college. Several reports of poisoning from these sources have come to the college this spring. The best preventative is to keep the stock away from the ripened pods, says Pieper.

Leaves of wild cherry trees are also poisonous and care should be taken to clean up fallen branches after storms or heavy winds.

Some of the more common poisonous spring weeds of Illinois are: patchmen's breeches, larkspur, buttercup and the roots of water hemlock. The roots of the hemlock are often uncovered by gully washing and apparently have an appetizing flavor. They are exceedingly toxic and cause death in a comparatively short time.

While ripened pods of honey locust trees are not ordinarily considered poisonous, there are indications of some danger from these pods so it will pay to keep them out of reach of livestock.

-M-

Food Costs Jump Only Half As High As U. S. Payrolls

Food prices, frequently discussed these days, may be going up, but during the past two years factory payrolls in the United States have increased nearly twice as fast as retail food prices, it is pointed out by R. W. Bartlett, of the Department of Agricultural Economics, College of Agriculture, University of Illinois.

The total cash income of factory workers in February, 1935, the most recent month for which figures are available, was \$613,000,000, which was an increase of \$252,000,000 over the amount for February, 1934. This was a net increase of 75 per cent. During this same period food prices increased only 34 per cent.

The total cost of living during February of this year was 13 per cent higher than during the same month of 1933. The very small increase in fuel, light and housing costs during the two-year period accounts for the very moderate increase in living costs.

For the city consumer, fuel and light costs went up about 1.4 per cent. Housing costs increased approximately 2.3 per cent. Clothing costs showed a greater increase with prices climbing 24.4 per cent during the two years.

## THE NEEDS OF RURAL ILLINOIS

Rural Illinois is a land of opportunity with rich resources and high potentialities. Following the general trend of progress in all lines of human endeavor, it is the duty of the Agricultural College, University of Illinois, to study the needs of the rural people and to provide for their betterment, education, and the betterment of the state.

Rural Illinois is a land of opportunity with rich resources and high potentialities. Following the general trend of progress in all lines of human endeavor, it is the duty of the Agricultural College, University of Illinois, to study the needs of the rural people and to provide for their betterment, education, and the betterment of the state.

This study is being conducted by the Agricultural College, University of Illinois, in cooperation with the State Board of Agriculture, the State Board of Education, and the State Board of Health. The study is being conducted by the Agricultural College, University of Illinois, in cooperation with the State Board of Agriculture, the State Board of Education, and the State Board of Health. The study is being conducted by the Agricultural College, University of Illinois, in cooperation with the State Board of Agriculture, the State Board of Education, and the State Board of Health.

Eight main areas of rural Illinois are being studied to determine the needs and wants of rural people. These are: 1. Education, 2. Health, 3. Housing, 4. Recreation, 5. Social Service, 6. Extension Service, 7. Rural Development, and 8. Rural Industry. The study is being conducted by the Agricultural College, University of Illinois, in cooperation with the State Board of Agriculture, the State Board of Education, and the State Board of Health. The study is being conducted by the Agricultural College, University of Illinois, in cooperation with the State Board of Agriculture, the State Board of Education, and the State Board of Health.

From the standpoint of the rural people's interests, the study is being conducted by the Agricultural College, University of Illinois, in cooperation with the State Board of Agriculture, the State Board of Education, and the State Board of Health. The study is being conducted by the Agricultural College, University of Illinois, in cooperation with the State Board of Agriculture, the State Board of Education, and the State Board of Health.

Dr. J. H. ... said, "The study is being conducted by the Agricultural College, University of Illinois, in cooperation with the State Board of Agriculture, the State Board of Education, and the State Board of Health. The study is being conducted by the Agricultural College, University of Illinois, in cooperation with the State Board of Agriculture, the State Board of Education, and the State Board of Health."

"Farming," he said, "offers you the opportunity of better food, better health, better living, better health and longer life, better recreation, better education, and better joy in your work and better family life."

"It is the duty of the Agricultural College, University of Illinois, to study the needs of the rural people and to provide for their betterment, education, and the betterment of the state. The study is being conducted by the Agricultural College, University of Illinois, in cooperation with the State Board of Agriculture, the State Board of Education, and the State Board of Health. The study is being conducted by the Agricultural College, University of Illinois, in cooperation with the State Board of Agriculture, the State Board of Education, and the State Board of Health."

Rural Communities Planning Center of Farm Training

Illinois farmers and homemakers are doing more and more of their own group planning right in their communities, according to D. E. Lindstrom, rural sociology extension specialist at the College of Agriculture, University of Illinois. Meetings were held in 1,000 rural communities in 1944 to assist in improving agriculture and homemaking through better utilization of programs and projects offered by the extension service of the agricultural college. This year the idea of group planning by rural community units is going ahead with new enthusiasm, he reported.

New community units are being organized to supplement those already established and county wide meetings are being initiated as a means of correlating the plans of the various units. In all of these activities the main thing is the use of organization to make extension work in planning and home-making more effective in the community.

As an example of the planning activities going on over the state this spring, Saline county community workers, in cooperation with the college, will hold a series of three meetings in each of eight communities during the spring and summer.

The first of the series will be held in the fall and will be devoted to discussions of AAA work and livestock raising. Monthly meetings of these communities will be held during which the outlook for grain prices, as well as the future of agricultural planning will be under discussion. The September meeting will discuss community organization and will also consider the livestock raising problem.

Interest in county wide meetings was illustrated recently when 100 people got together in Adam Island to discuss further plans for the organization of community units, to correlate community plans and to inaugurate educational programs. A similar meeting is planned for Union county with eight communities scheduled to organize this spring.

Five communities in Pulaski and Adams counties will soon hold meetings to discuss the many problems related to extension work and to learn more about present and future AAA programs.

Units of long range planning which are seeking as guidelines for the newly organized groups include 4 in Champaign county, 17 in DeWitt, 10 in Illinois, 11 in Randolph, 1 in Sangamon, 11 in Tipton, 1 in Washington, eight in York county in Missouri and a range of from three to 16 each in 7 other counties.

The community unit is the ideal organization for promoting better farming and homemaking and community betterment, Lindstrom believes. Activities this spring indicate a definite trend among rural folk of Illinois to do more of this kind of planning, he said.

-11-

No Magic Method or Short Cuts For Reducing Weight

Women, and even men, who seek to lose weight by means of a fad diet will find that there are no safe short cuts and no magic methods by which weight can be lost, according to a new circular, "Some Good Fat Diets and How to Obtain Them," which has just been issued by the College of Agriculture, University of Illinois. Miss Harriet T. Barts, assistant professor of dietetics, is author.

While there is no magic method, it is not necessary to resort to semi-starvation or to peculiar combinations of foods entirely unlike an ordinary diet in order to lose weight, Miss Barts explains. Planning a sane and sound diet is vital, for such a diet differs from a fad diet for a person of so-called normal weight only in the number of calories it supplies, she said. Fat-free diets for an entire week are printed in the circular.

### Young People's Work To Be Further Advanced

Work with rural young people, on the new war activities of county fairs and home advisors and the extension service of the College of Agriculture, University of Illinois, has been given new impetus in an announcement by Dean W. Mumford. Two staff members of the college, E. F. Randall and Miss Cleo Filippopoulou, formerly 4-H club workers, have been assigned to give their full time and attention to work with rural young adults.

Programs for rural young people are well under way in 48 different counties of the state as a result of a rural leadership by the extension service of the agricultural college and county farm and home advisors. Now more than a county is being planned to start such activities, ranging from the turnout at the recent second annual young people's rural life conference held at Urbana, Ill.

Planning and inaugurating programs for rural young adults is one of the most significant developments in extension service work in the agricultural college, Dean Mumford said. The program is designed to meet the needs and wants of these people beyond the 4-H club and the present educational and training field.

Holding of the rural life and rural young people's rural life conference at the agricultural college is one step in the development of the program. A total of 100 delegates from 48 counties attended.

A number of projects already have been set on foot and being arranged by the extension service of the agricultural college from which young people in the different counties can make selections for a program of their own liking. In their discussions at the recent conference the young people will make a record of their interests concerning such things as land, financial aid, their interests to be considered in setting up farming, soil conservation, home reviews, recreation and farm planning.

-14-

### Neglect To a Fire As Destroyer Of Illinois Buildings

At the present rate, it would require 250 years for fire to destroy all of the farm buildings in Illinois. Neglect would do the job in but one-fifth the time, or 50 years, declares W. A. Foster, rural architect at the College of Agriculture, University of Illinois.

Neglect, while less spectacular than fire, does a far more damage to Illinois buildings every year, states Foster. One of the most important things neglected is the proper use of paint. Paint is an excellent preservative of both woods and metals. It is even useful in preserving stone by protecting against oxidation and the consequent damage by freezing and thawing.

Properly applied and in the right colors, paint not only adds to the life of farm buildings but also adds to their beauty.

Good roofs and eavest overhanging are also features in preserving the life of the buildings. A good roof prevents damage by heading rains and snow from reaching the inside timbers. In addition, it protects the hay, feed and other things stored in the building. A roof that is leaking, a damaged portion of a building is like a rotten apple. If it is not promptly removed or repaired, the fungus will not spread, but neglect will cause the damage to increase.

Wind takes its toll of buildings in the state, but even this damage can be decreased through proper design and management, Foster points out. Buildings should be placed so that large flat surfaces will not be exposed to prevailing winds. Keep the doors carefully closed keep the wind from "getting under" the buildings and possibly wrecking it or at least wrenching the frame apart.

Since buildings, like automobiles, are bound to last a long time, they can be kept in fine shape only by careful maintenance and the installation of modern equipment.

-15-

### Termite Collecting Heavier Tax Than Any Other Pest

While the clinician topped the list of tax collectors with an estimated assessment of \$50,000,000 against Illinois agriculturists in 1924, the termites outranked the chinch bug in point of average annual cost to citizens of the state over a period of 15 years. That is shown by W. F. Flint, entomologist of the College of Agriculture, University of Illinois, and the Illinois State Natural History Survey.

Termit infestation is especially bad in southern and central Illinois where houses, barns and fence posts are being destroyed year after year by these insidious little wood-eating insects.

Unable to enter in bright sunlight, the insects take their entry into the wooden parts of buildings and other structures from the ground. The entrance or main nest is always in the ground, and it is from this nest that the termites enter the building. Consequently, no use of concrete or metal base in the foundations will usually prevent infestation.

Keeping the ground surface around buildings, barns and other buildings well mowed and stamped also will help in preventing termite infestation and destruction.

Infestation is often first indicated by swarms of winged termites, flying-winged insects about a third of an inch long which suddenly appear in great numbers from the building. These swarms usually consist of females or young winged adults. They fly from the nest to start a new colony. If they appear, the premises should be searched, and the nest destroyed if possible.

Building codes should contain provisions for the protection of buildings from termite damage, Flint believes. However, where such provisions are not contained in the codes, they should specify that the contractor in charge of building termite-proof. A state of information on the control of termites can be applied from the Agricultural College of the Illinois State Natural History Survey.

-M-

### Leaf Hopper Heavy Tax Borne On By Home Owners In Illinois

It is the only insect pest in Illinois that has not been leaf hoppers will be identified early to more serious damage to the crop acreage this year. However, the average frequently infested acreage by 50 percent, and that the exterminations for dusting or spraying the home with a copper compound will help to crop insurance, according to E. W. Shreve, assistant entomologist of the Illinois State Natural History Survey.

Unprotected home infested 70 percent less this year than had been sprayed or dusted in tests conducted at the Cook County branch experiment station of the College of Agriculture, University of Illinois.

A copper dust containing tobacco and gypsum is one of the dusts and sprays that has proved effective in controlling the leaf hopper during the tests. It was applied at the rate of about 10 to 15 pounds to the acre. Applications were made five times, beginning when the plants were well above the ground and continuing until five applications were made.

The 20-50 Bordeaux spray also proved effective, but was not quite so good as the copper dust. Nicotine sulphate spray had little value in controlling leaf hoppers.

Home leaf hoppers do not hibernate in the winter months of Illinois, but migrate to the home late in the spring. They constitute one of the most serious of home and frequently infest Illinois gardens in heavy numbers.

## Control of Army Worms Through the Use of Bait

One of the most serious army worm outbreaks in Illinois occurred in recent years in 1908. It is the most serious pest of the corn crop and is on record to have done more damage to the corn crop than any other pest. The most recent list of Illinois army worm outbreaks is given by the Illinois Agricultural Experiment Station, University of Illinois.

Army worms are the most common pest of the corn crop in Illinois. They are on record to have done more damage to the corn crop than any other pest. The most recent list of Illinois army worm outbreaks is given by the Illinois Agricultural Experiment Station, University of Illinois.

The most common pest of the corn crop in Illinois is the army worm. It is on record to have done more damage to the corn crop than any other pest. The most recent list of Illinois army worm outbreaks is given by the Illinois Agricultural Experiment Station, University of Illinois.

A new bait, called "Army Worm Bait," was developed by the Illinois State Natural History Survey, and is available for use in the State. It is a bait which is made of molasses and is used to control army worms. The bait is made of molasses and is used to control army worms. The bait is made of molasses and is used to control army worms.

Which bait it is used should be applied evenly and uniformly over the ground at the rate of one quart per acre. If the worms are on the corn, the bait should be sown in the rows and the corn should be kept free of weeds. The molasses bait should be used in the rows of the corn. The bait should be used in the rows of the corn.

Either of the baits may be used in the rows of the corn. If no more than the first growth of corn is out, the bait is not needed. In most cases, the bait should be used in the rows of the corn. The bait should be used in the rows of the corn.

Young army worms are very voracious and will eat up the corn crop. They are on record to have done more damage to the corn crop than any other pest. The most recent list of Illinois army worm outbreaks is given by the Illinois Agricultural Experiment Station, University of Illinois.

Value of Zinc Sulphate Established in U. S. Tests

Possibilities of zinc sulphate as a corrective for the damage that widely-used arsenical sprays cause to Illinois' four million apple trees have now been more fully established as a result of three years' experiments by the College of Agriculture, University of Illinois. Results of the experiments are reported in a new bulletin just issued by the college, "The Role of Zinc Sulphate in Fruit Sprays," by H. J. Kadwa and T. W. Anderson.

Although it is not to be construed as the value of zinc sulphate as a corrective agent in spray mixtures, they also are listed in this bulletin as a little value as a fungicide or bactericide for combating the diseases common to the state's apple raising industry. Neither all the material saw conditions of use of having value as a plant nutrient in Illinois conditions, except in later fruit tests. The real value of zinc sulphate in the Illinois apple spray is shown in its ability to protect injury to apple trees from lead arsenate-like sprays.

The lead arsenate-lime spray mixture is long known as a good remedy for a season against various insect and disease attacks on apple trees. However, this mixture may cause a serious injury to trees when used in high dilutions. The injuries include bud killing, leaf injury, bark damage and stem and limb girdling of the entire tree, according to the bulletin.

This injury is caused by the liberation of hydrochloric acid through the rapid carbonization of the lime. The addition of zinc sulphate to the spray mixture cuts down the amount of carbonic acid and prevents the formation of arsenic acid, which is the direct cause of the injury. The zinc sulphate also precipitates an insoluble zinc arsenate whenever arsenic acid is formed.

The most suitable formula for the zinc sulphate mixture containing the corrective zinc sulphate is 1 pound zinc sulphate, 1 pound arsenic sulphide and 5 pounds of lead arsenate to 100 gallons of water.

Soil Testing Proves Benefits of Limestone

With a few exceptions the larger acreages of farms located in Illinois farms this spring, thousands of farmers took the "sweetening" out of their plantings by testing the soil for acidity, it is reported by L. H. Lindley, soils extension specialist at the College of Agriculture, University of Illinois.

Profound among those who tested their soils were the farmers of Whiteside county, according to a report from Farm Advisor F. W. Shanon. Another leading county in this work was Madison county. During March, 1934, 100 tons of limestone were used to sweeten the soil for alfalfa and clover planting, said Farm Advisor T. W. Hart.

These farmers have learned, along with thousands of others in the state, that the chances of getting a good stand of alfalfa or clover are much better if the soil is tested and sweetened with limestone if necessary before being seeded. This is especially true during dry seasons such as last, Lindley said.

Occasionally, when there is plenty of rain, alfalfa and clover may make a fair stand even though the soil is somewhat sour. During severe seasons, however, the crops will turn out in soil soils. The weather usually was the blame when the soil conditions really were at fault, said Lindley.

Where the soil is tested and sweetened, as was done by the Whiteside county farmers, vigorous growth-resistant plants are produced, and there is a good chance of getting a supply of food in years when the corn and oats are stopped by blights there. This was well illustrated in 1934, Lindley said.

Skilled Feeding with Most Out of Winter and Spring

With high prices for corn and alfalfa, and high ration they are a year ago, Illinois hogs are raised in a profitable manner, especially if they get feeding costs through the use of alfalfa and protein supplements, in the opinion of T. E. Carroll and W. D. G. Lewis, of the Swine Division, College of Agriculture, University of Illinois.

The possibility of getting feed costs through the use of alfalfa, and protein supplements, has been by hogs, recently a most lower feeding costs and at the college, winter ration.

In six lots of hogs, each group being on the basis of current prices, were made by the lot fed corn and protein at the cost of 15 cents of corn to 1 of protein supplement and having a ration of alfalfa. The cost for 100 pounds gain, considering the lot that was spring's price, was \$7.40. The lot fed a ration of corn and protein and alfalfa, cost the same time as the lot at a cost of \$7.40. The lot that was fed alfalfa, cost the same time as the lot and 1.5 tons to the acre, but from the same ration was a considerable increase.

Allowing the hogs a free choice of corn, protein supplement and alfalfa cut down the supplement cost but increased the cost of corn, the cost of the ration costing \$7.00. Corn and alfalfa also were fed, the cost of the ration was \$7.00, but the hogs were better and they were longer in finishing. This is a considerable increase since early sales of hogs are the most profitable during the year.

The most expensive ration, on the basis of the present ratio between corn and protein supplement prices, was that of a high ration of corn and no alfalfa ration. At present prices, this ration cost about 10 pounds of gain and required from seven to ten days longer to finish the hogs.

Generally speaking, the 15-cents corn ration is a good one to use along with alfalfa protein supplement and alfalfa. The cost of the ration is low, gains are made rapidly and the alfalfa gives the producer some income above the sale of his hogs.

Horse Cereals Brackets Outlook For 1934-35

Colt. now being produced by Illinois farmers are almost certain to find a good market at present prices by the time they are ready to work, in the opinion of E. T. Robbins, animal husbandry extension specialist at the College of Agriculture, University of Illinois.

Horse numbers in the United States have been increasing steadily for the past 17 years. During most of that time the increase amounted to about a half million a year, but has slowed down recently with last year's increase amounting to 1 1/2 million. With the horse trade again averaging about \$2000 a year, indications are that prices will continue to be good for another few years.

The decrease in numbers came about as a result of high-priced feed and the replacement of horses and mules by tractors and trucks. During recent years, however, feed prices have been low, making the horse a cheaper source of power than the tractor on many farms. This feature alone is important, which increases of three or more per cent. Higher prices have been received at the market this spring, and more horses and mules have been sold than for several years. Horse raisers and the farmers who buy them, as shown by the fact that most of the horses are going to the country, Robbins said.

## New Bit Offers Better Protection Against Grasshopper Damages

Chances are that the pestiferous army worms, cutworms and grasshoppers which are at this time causing such damage through the use of a new poisoned bait which has been tested by the Illinois State Natural History Survey, as reported by J. H. Biggar, assistant entomologist, at the College of Agriculture, University of Illinois.

With army worms and cutworms being so scarce in the state this year, the new bait will save farmers money and crops if it proves successful under Illinois conditions, Biggar indicates.

The new bit, which was given tests in 1913 and 1914 tests, is a variation of the time-trial bait known as No. 1. The main difference is that lubricating oil is substituted for the kerosene oil used. The bait is made by combining 25 pounds of bran, 2 pounds of feather, 100 grains of arsenic, and 100 drops of lubricating oil of S. A. E. No. 1 viscosity.

In this bait the oil replaces two parts of m-larvae and three gallons of water. It is easier to mix and apply, may be applied any time of day or night and is longer lasting. A 10-foot strip of the bait, 20 feet wide, was found, during the tests, to be entirely satisfactory, but no larval counts were made to be sure.

While the oil bait is still in the experimental stage, it was tested side by side with the regular poisoned bait during 1913 and 1914 and gave just as satisfactory results against grasshopper infestations, Biggar said. In 1913 the bait was tried against cutworms in Sangamon, Morgan and Pike counties with good results. While the new bait has not been thoroughly tested against army worms, experience with other bits leads Biggar to think that the oil bait will also be satisfactory against these pests.

## Destruction of Corn Weeds Helps Check Flea Beetles

Thorough destruction of weeds in corn fields is the only effective means of protecting the young corn from flea beetles, which threaten to be plentiful this spring, according to J. H. Biggar, Illinois State Natural History Survey entomologist, cooperating with the College of Agriculture, University of Illinois. Abundant rainfall and early weed growth before the corn was planted has encouraged the beetles, since they live on weeds until the corn starts growing.

The flea beetle is a tiny black or greenish insect and derives its name from its habit of jumping like a flea when disturbed. Until the corn is up, the insect feeds on such weeds as purslane, lamb's quarter, ragweed and smart weed. As soon as the corn grows, the beetle turns its attention to the corn leaves, eating small round holes in them.

Where the flea beetles are numerous, they chew the corn leaves so seriously that the plants lose vitality, turn yellow and often die.

Keeping weeds out of the field before and after the corn is planted will do much toward muddling the insects, since they make their homes in the weeds until the corn appears above the ground. Vigorous, fast growing corn will often outgrow the beetle. Hence, it is advisable in many cases to delay planting until the ground is warm.

Higher Priced and the Increase in Demand for a Workable and Enduring

Higher priced and the increase in demand for a workable and enduring interest to the Illinois Farm Building Contest which will be held against its peers for the twenty-second year by the College of Agriculture, University of Illinois, it is sponsored by E. T. Atkins, livestock and poultry specialist.

Many contests are already being held, and their success will be largely determined by the arrangements that can be made, Robbins reports. The opening contest this year will be at the Chicago Tribune on West Washington, June 15. August, however, seems to be the favorite month with six shows scheduled. The titles will be held at the Perry County Fair, Lincolnville, August 14; Edwards County Fair, Albion, August 15; Indiana County Fair, Elford, August 16; Illinois State Fair, Springfield, August 20 and 21; Warren County Fair, Roseville, August 22, and the St. Joseph Agricultural Fair, St. Joseph, August 27. Other contests are scheduled for the Jackson County Fair, Alton, September 3; DeKalb County Fair, Sandwich, September 4; Edwards County Fair, Princeton, September 5, and De Witt County Fair, Danvers City, September 6.

The contests are held by a national judging body organized to study the characteristics which influence the breeding of stock and milk production. The contests start at the college and the champion, grand champion and reserve champions are recorded for their 1,500 hours. Pencil records of the contests are kept at the year's end by one of the university's departments.

Fighting contests are held for the most part for the purpose of determining the interest of both team owners and spectators. In fact, it is when the contests are first classes of competition is divided into two classes, the light teams weighing less than 1,000 lbs. and the other for teams weighing 1,000 lbs. or more.

The light class starts on August 15, and by William D. Williams, a representative of the Illinois State Fair, still stands as the champion of the light class. The champion of the heavy class is a champion of the Illinois State Fair, Springfield.

John Crawford, of Peoria, is the champion of the heavy class. He is a champion in the heavy class. His record is 1,000 lbs. at the Chicago Tribune contest in August, 1910. He is the champion, weighing 1,000 lbs., 1910, 1911, 1912, 1913, 1914, 1915, 1916, 1917, 1918, 1919, 1920, 1921, 1922, 1923, 1924, 1925, 1926, 1927, 1928, 1929, 1930, 1931, 1932, 1933, 1934, 1935, 1936, 1937, 1938, 1939, 1940, 1941, 1942, 1943, 1944, 1945, 1946, 1947, 1948, 1949, 1950, 1951, 1952, 1953, 1954, 1955, 1956, 1957, 1958, 1959, 1960, 1961, 1962, 1963, 1964, 1965, 1966, 1967, 1968, 1969, 1970, 1971, 1972, 1973, 1974, 1975, 1976, 1977, 1978, 1979, 1980, 1981, 1982, 1983, 1984, 1985, 1986, 1987, 1988, 1989, 1990, 1991, 1992, 1993, 1994, 1995, 1996, 1997, 1998, 1999, 2000, 2001, 2002, 2003, 2004, 2005, 2006, 2007, 2008, 2009, 2010, 2011, 2012, 2013, 2014, 2015, 2016, 2017, 2018, 2019, 2020, 2021, 2022, 2023, 2024, 2025, 2026, 2027, 2028, 2029, 2030, 2031, 2032, 2033, 2034, 2035, 2036, 2037, 2038, 2039, 2040, 2041, 2042, 2043, 2044, 2045, 2046, 2047, 2048, 2049, 2050, 2051, 2052, 2053, 2054, 2055, 2056, 2057, 2058, 2059, 2060, 2061, 2062, 2063, 2064, 2065, 2066, 2067, 2068, 2069, 2070, 2071, 2072, 2073, 2074, 2075, 2076, 2077, 2078, 2079, 2080, 2081, 2082, 2083, 2084, 2085, 2086, 2087, 2088, 2089, 2090, 2091, 2092, 2093, 2094, 2095, 2096, 2097, 2098, 2099, 2100, 2101, 2102, 2103, 2104, 2105, 2106, 2107, 2108, 2109, 2110, 2111, 2112, 2113, 2114, 2115, 2116, 2117, 2118, 2119, 2120, 2121, 2122, 2123, 2124, 2125, 2126, 2127, 2128, 2129, 2130, 2131, 2132, 2133, 2134, 2135, 2136, 2137, 2138, 2139, 2140, 2141, 2142, 2143, 2144, 2145, 2146, 2147, 2148, 2149, 2150, 2151, 2152, 2153, 2154, 2155, 2156, 2157, 2158, 2159, 2160, 2161, 2162, 2163, 2164, 2165, 2166, 2167, 2168, 2169, 2170, 2171, 2172, 2173, 2174, 2175, 2176, 2177, 2178, 2179, 2180, 2181, 2182, 2183, 2184, 2185, 2186, 2187, 2188, 2189, 2190, 2191, 2192, 2193, 2194, 2195, 2196, 2197, 2198, 2199, 2200, 2201, 2202, 2203, 2204, 2205, 2206, 2207, 2208, 2209, 2210, 2211, 2212, 2213, 2214, 2215, 2216, 2217, 2218, 2219, 2220, 2221, 2222, 2223, 2224, 2225, 2226, 2227, 2228, 2229, 2230, 2231, 2232, 2233, 2234, 2235, 2236, 2237, 2238, 2239, 2240, 2241, 2242, 2243, 2244, 2245, 2246, 2247, 2248, 2249, 2250, 2251, 2252, 2253, 2254, 2255, 2256, 2257, 2258, 2259, 2260, 2261, 2262, 2263, 2264, 2265, 2266, 2267, 2268, 2269, 2270, 2271, 2272, 2273, 2274, 2275, 2276, 2277, 2278, 2279, 2280, 2281, 2282, 2283, 2284, 2285, 2286, 2287, 2288, 2289, 2290, 2291, 2292, 2293, 2294, 2295, 2296, 2297, 2298, 2299, 2300, 2301, 2302, 2303, 2304, 2305, 2306, 2307, 2308, 2309, 2310, 2311, 2312, 2313, 2314, 2315, 2316, 2317, 2318, 2319, 2320, 2321, 2322, 2323, 2324, 2325, 2326, 2327, 2328, 2329, 2330, 2331, 2332, 2333, 2334, 2335, 2336, 2337, 2338, 2339, 2340, 2341, 2342, 2343, 2344, 2345, 2346, 2347, 2348, 2349, 2350, 2351, 2352, 2353, 2354, 2355, 2356, 2357, 2358, 2359, 2360, 2361, 2362, 2363, 2364, 2365, 2366, 2367, 2368, 2369, 2370, 2371, 2372, 2373, 2374, 2375, 2376, 2377, 2378, 2379, 2380, 2381, 2382, 2383, 2384, 2385, 2386, 2387, 2388, 2389, 2390, 2391, 2392, 2393, 2394, 2395, 2396, 2397, 2398, 2399, 2400, 2401, 2402, 2403, 2404, 2405, 2406, 2407, 2408, 2409, 2410, 2411, 2412, 2413, 2414, 2415, 2416, 2417, 2418, 2419, 2420, 2421, 2422, 2423, 2424, 2425, 2426, 2427, 2428, 2429, 2430, 2431, 2432, 2433, 2434, 2435, 2436, 2437, 2438, 2439, 2440, 2441, 2442, 2443, 2444, 2445, 2446, 2447, 2448, 2449, 2450, 2451, 2452, 2453, 2454, 2455, 2456, 2457, 2458, 2459, 2460, 2461, 2462, 2463, 2464, 2465, 2466, 2467, 2468, 2469, 2470, 2471, 2472, 2473, 2474, 2475, 2476, 2477, 2478, 2479, 2480, 2481, 2482, 2483, 2484, 2485, 2486, 2487, 2488, 2489, 2490, 2491, 2492, 2493, 2494, 2495, 2496, 2497, 2498, 2499, 2500, 2501, 2502, 2503, 2504, 2505, 2506, 2507, 2508, 2509, 2510, 2511, 2512, 2513, 2514, 2515, 2516, 2517, 2518, 2519, 2520, 2521, 2522, 2523, 2524, 2525, 2526, 2527, 2528, 2529, 2530, 2531, 2532, 2533, 2534, 2535, 2536, 2537, 2538, 2539, 2540, 2541, 2542, 2543, 2544, 2545, 2546, 2547, 2548, 2549, 2550, 2551, 2552, 2553, 2554, 2555, 2556, 2557, 2558, 2559, 2560, 2561, 2562, 2563, 2564, 2565, 2566, 2567, 2568, 2569, 2570, 2571, 2572, 2573, 2574, 2575, 2576, 2577, 2578, 2579, 2580, 2581, 2582, 2583, 2584, 2585, 2586, 2587, 2588, 2589, 2590, 2591, 2592, 2593, 2594, 2595, 2596, 2597, 2598, 2599, 2600, 2601, 2602, 2603, 2604, 2605, 2606, 2607, 2608, 2609, 2610, 2611, 2612, 2613, 2614, 2615, 2616, 2617, 2618, 2619, 2620, 2621, 2622, 2623, 2624, 2625, 2626, 2627, 2628, 2629, 2630, 2631, 2632, 2633, 2634, 2635, 2636, 2637, 2638, 2639, 2640, 2641, 2642, 2643, 2644, 2645, 2646, 2647, 2648, 2649, 2650, 2651, 2652, 2653, 2654, 2655, 2656, 2657, 2658, 2659, 2660, 2661, 2662, 2663, 2664, 2665, 2666, 2667, 2668, 2669, 2670, 2671, 2672, 2673, 2674, 2675, 2676, 2677, 2678, 2679, 2680, 2681, 2682, 2683, 2684, 2685, 2686, 2687, 2688, 2689, 2690, 2691, 2692, 2693, 2694, 2695, 2696, 2697, 2698, 2699, 2700, 2701, 2702, 2703, 2704, 2705, 2706, 2707, 2708, 2709, 2710, 2711, 2712, 2713, 2714, 2715, 2716, 2717, 2718, 2719, 2720, 2721, 2722, 2723, 2724, 2725, 2726, 2727, 2728, 2729, 2730, 2731, 2732, 2733, 2734, 2735, 2736, 2737, 2738, 2739, 2740, 2741, 2742, 2743, 2744, 2745, 2746, 2747, 2748, 2749, 2750, 2751, 2752, 2753, 2754, 2755, 2756, 2757, 2758, 2759, 2760, 2761, 2762, 2763, 2764, 2765, 2766, 2767, 2768, 2769, 2770, 2771, 2772, 2773, 2774, 2775, 2776, 2777, 2778, 2779, 2780, 2781, 2782, 2783, 2784, 2785, 2786, 2787, 2788, 2789, 2790, 2791, 2792, 2793, 2794, 2795, 2796, 2797, 2798, 2799, 2800, 2801, 2802, 2803, 2804, 2805, 2806, 2807, 2808, 2809, 2810, 2811, 2812, 2813, 2814, 2815, 2816, 2817, 2818, 2819, 2820, 2821, 2822, 2823, 2824, 2825, 2826, 2827, 2828, 2829, 2830, 2831, 2832, 2833, 2834, 2835, 2836, 2837, 2838, 2839, 2840, 2841, 2842, 2843, 2844, 2845, 2846, 2847, 2848, 2849, 2850, 2851, 2852, 2853, 2854, 2855, 2856, 2857, 2858, 2859, 2860, 2861, 2862, 2863, 2864, 2865, 2866, 2867, 2868, 2869, 2870, 2871, 2872, 2873, 2874, 2875, 2876, 2877, 2878, 2879, 2880, 2881, 2882, 2883, 2884, 2885, 2886, 2887, 2888, 2889, 2890, 2891, 2892, 2893, 2894, 2895, 2896, 2897, 2898, 2899, 2900, 2901, 2902, 2903, 2904, 2905, 2906, 2907, 2908, 2909, 2910, 2911, 2912, 2913, 2914, 2915, 2916, 2917, 2918, 2919, 2920, 2921, 2922, 2923, 2924, 2925, 2926, 2927, 2928, 2929, 2930, 2931, 2932, 2933, 2934, 2935, 2936, 2937, 2938, 2939, 2940, 2941, 2942, 2943, 2944, 2945, 2946, 2947, 2948, 2949, 2950, 2951, 2952, 2953, 2954, 2955, 2956, 2957, 2958, 2959, 2960, 2961, 2962, 2963, 2964, 2965, 2966, 2967, 2968, 2969, 2970, 2971, 2972, 2973, 2974, 2975, 2976, 2977, 2978, 2979, 2980, 2981, 2982, 2983, 2984, 2985, 2986, 2987, 2988, 2989, 2990, 2991, 2992, 2993, 2994, 2995, 2996, 2997, 2998, 2999, 3000, 3001, 3002, 3003, 3004, 3005, 3006, 3007, 3008, 3009, 3010, 3011, 3012, 3013, 3014, 3015, 3016, 3017, 3018, 3019, 3020, 3021, 3022, 3023, 3024, 3025, 3026, 3027, 3028, 3029, 3030, 3031, 3032, 3033, 3034, 3035, 3036, 3037, 3038, 3039, 3040, 3041, 3042, 3043, 3044, 3045, 3046, 3047, 3048, 3049, 3050, 3051, 3052, 3053, 3054, 3055, 3056, 3057, 3058, 3059, 3060, 3061, 3062, 3063, 3064, 3065, 3066, 3067, 3068, 3069, 3070, 3071, 3072, 3073, 3074, 3075, 3076, 3077, 3078, 3079, 3080, 3081, 3082, 3083, 3084, 3085, 3086, 3087, 3088, 3089, 3090, 3091, 3092, 3093, 3094, 3095, 3096, 3097, 3098, 3099, 3100, 3101, 3102, 3103, 3104, 3105, 3106, 3107, 3108, 3109, 3110, 3111, 3112, 3113, 3114, 3115, 3116, 3117, 3118, 3119, 3120, 3121, 3122, 3123, 3124, 3125, 3126, 3127, 3128, 3129, 3130, 3131, 3132, 3133, 3134, 3135, 3136, 3137, 3138, 3139, 3140, 3141, 3142, 3143, 3144, 3145, 3146, 3147, 3148, 3149, 3150, 3151, 3152, 3153, 3154, 3155, 3156, 3157, 3158, 3159, 3160, 3161, 3162, 3163, 3164, 3165, 3166, 3167, 3168, 3169, 3170, 3171, 3172, 3173, 3174, 3175, 3176, 3177, 3178, 3179, 3180, 3181, 3182, 3183, 3184, 3185, 3186, 3187, 3188, 3189, 3190, 3191, 3192, 3193, 3194, 3195, 3196, 3197, 3198, 3199, 3200, 3201, 3202, 3203, 3204, 3205, 3206, 3207, 3208, 3209, 3210, 3211, 3212, 3213, 3214, 3215, 3216, 3217, 3218, 3219, 3220, 3221, 3222, 3223, 3224, 3225, 3226, 3227, 3228, 3229, 3230, 3231, 3232, 3233, 3234, 3235, 3236, 3237, 3238, 3239, 3240, 3241, 3242, 3243, 3244, 3245, 3246, 3247, 3248, 3249, 3250, 3251, 3252, 3253, 3254, 3255, 3256, 3257, 3258, 3259, 3260, 3261, 3262, 3263, 3264, 3265, 3266, 3267, 3268, 3269, 3270, 3271, 3272, 3273, 3274, 3275, 3276, 3277, 3278, 3279, 3280, 3281, 3282, 3283, 3284, 3285, 3286, 3287, 3288, 3817, 3818, 3819, 3820, 3821, 3822, 3823, 3824, 3825, 3826, 3827, 3828

### Four Shifts Are Made Among Farm And Home Advisers

With the appointment of Miss Bernice Smith as home adviser of Greene county, 10 Illinois counties and a law carrying on organized home services extended over the direction of the College of Agriculture, University of Illinois, it is announced by Mrs. Kathryn Van Allen Burns, state leader of home extension.

Three changes during the 9 farm advisers were in serving 10 of the 107 counties of the state in agricultural extension service were also have been announced by Prof. D. C. Spittler, state leader of farm advisers.

Miss Smith, the new home adviser of Greene county, was graduated from the University of Illinois in 1927 and has been teaching school at Illinois. She is the thirty-fifth home adviser in the state. Some of them have two counties, which accounts for the fact that a total of 100 counties have this service.

In the ranks of the farm advisers, E. C. Johnston has been named as a farm adviser in Piatt county to succeed E. G. Irving, who resigned April 30. During the past two years Mr. Johnston has been service as extension agent in the home extension program and more recently has been connected with the office of A. J. Curritt, state agricultural statistician, Springfield. Mr. Johnston started work in May 1.

H. H. Gordon, farm adviser for Polk and Alexander counties, resigned April 30 to accept the position of assistant county extension agent in the AAA land office section. He will be in charge of the southern Illinois forest project and will have headquarters at Anna.

W. E. Gould, Johnson county farm adviser, resigned May 1 to become project manager of the Rabbits project, Ribbs, for the Illinois Rural Rehabilitation Corporation. Successors to Mr. Gordon and Mr. Gould have not yet been selected.

### Added Nitrate May Be Needed In Cabbages This Spring

With rainfall in most sections of Illinois above normal, it may be necessary to apply nitrate or soda to many cabbage fields this spring, in the opinion of E. L. Weaver of the vegetable gardening division, College of Agriculture, University of Illinois. The lack of nitrates in the soil will be evidenced by the yellow color and stunted growth of the young plants.

This shortage of nitrate is especially apparent when the weather is cool as well as damp. Such weather slows down the activity of soil organisms and is one of the main causes for a nitrate deficiency. On the other hand, hot weather and lack of moisture, such as was the case in 1924 bring about an accumulation of nitrate on the surface of the soil. Any addition of nitrate fertilizer under such conditions will probably damage the crop.

Whenever yellow color and lack of growth indicate shortage of nitrates this year, the deficiency can be supplied through the use of nitrogen fertilizer such as nitrate of soda, Neway acid. It is usually more satisfactory to make two applications over a period of several days with the total amounting to about one to two pounds to the acre.

Fortunately, the lack of nitrate does not permanently injure the cabbage plants if the deficiency is taken care of before the plants get too young. In some instances nitrate such as are contained in the fertilizer dissolved readily and so is immediately available to plant food provided there is sufficient water in the soil.

Cabbage plants supplied with nitrate and fertilizer have produced better crops and have matured earlier than the plants which were grown without the nitrate fertilizer. In tests conducted at the college experimental station.

## New Illinois Mark in Dairying Tests—Highest Records

Despite unprecedented drought and food shortages last year, a new state standard which has anything but its equal in the past 50 years was set for milk and butterfat production by Illinois dairymen. It is announced by Prof. C. C. Fenske and J. G. Cash, dairy specialists at the College of Agriculture, University of Illinois.

The highest average production in the 40-year history of dairy herd improvement association work was made in 1926 by the 298 cows belonging to three associations, it is shown in the annual report which Rhode and Cash have just released on the work of these groups. The average for each cow was 7,471 pounds of milk and 324.9 pounds of butterfat.

During the same year the average production for all cows in the United States slipped to the lowest level in 20 years. The estimated average production of all cows in the state is estimated at about 140 pounds of butterfat.

By comparison with these marks, the new state record for the association herds is a tribute to the progress which the member dairymen are making toward more profitable production through better feeding, breeding and management of their herds, Rhode and Cash pointed out.

More than two-thirds, or 67%, of the association herds had an average of 300 pounds or more of butterfat for each cow.

Out of all the 20,400 cows that were tested for milk and fat yield by the association, the highest producing was a general Friesian in the herd of Mooseheart Farm, Mooseheart, that produced 117 tons of milk and 374 pounds of butterfat during the year. The Ellwood & Nelson herd, DeKalb, had the second highest producing cow; Mooseheart, third and fourth; Red River Farm, Byron, fifth; Ellwood & Nelson, sixth; Mooseheart, seventh; H. G. Fries, Altamont, eighth; Gullback & Lange, Marseilles, ninth; and Mooseheart, tenth.

The highest producing cow in the grade-cow group also was from Mooseheart. She had a record of 5,187 pounds of milk and 730 pounds of fat. Zimm's Dairy, Washington, had the second best cow in the grade class; Illinois State Penitentiary, Stateville, third; F. S. Pries, Caledonia, fourth; and Alexander Garnsey Farm, Bloomington, fifth.

As to herd averages, Mooseheart Farm and the Palmetto Farm No. 1, Palmetto, tied for first place with butterfat production averages of 351.8 pounds a cow. This is the fourth consecutive average of more than 300 pounds for the Palmetto herd. Six of the top herds were in the class of those having more than 10 cow years. Other list herds in the class included the herds of C. J. McIord, Newton, third; John Ellsworth, Harvard, fourth; and Gullback & Lange, fifth.

In the class of herds having from five to ten cow years, the herd of Oscar Anderson, Simonark, was first with an average of 311.6 pounds of butterfat. C. W. Guthrie, Charleston, was second; H. G. Fries, third; J. G. Keeboon, Gifford, fourth; and Keenan Brothers, Island, fifth.

Enter Supply of Milk Is Merited For Jan. 1933

Among the most meritorious to the late Miss Jane Adams, founder and social activist at Deer Grove, Chicago, will be the pioneering work which was done about 4 years ago in connection with the College of Agriculture, University of Illinois for the improvement of its milk supply.

Present milk surveys show a marked improvement in their communities. Have their field trials in this country, it is credited to Dr. F. H. Tracy, associate chief in dairy experiments at the college. Indirectly, this work and its subsequent developments have benefited milk consumers in many other cities, he said.

Alarmed at the quality of milk being offered to residents in the vicinity of Full House, the late Miss Adams in 1928 enlisted the cooperation of the experiment station, College of Agriculture, University of Illinois. With the work was carried on, she, with Dr. H. S. Grindley, professor emeritus of animal nutrition, reported their findings in Circular No. 11, issued in December, 1928, by the experiment station, on the subject, "A Study of the Milk Supply of Chicago."

"Overwhelming proof" that the milk supply of Chicago was remarkably poor was presented by the authors, they held that this was an inalienable condition should be remedied immediately and urged that immediate action be taken to improve the local milk supply then going to Chicago people.

Since then there has been steady improvement in the supply, the most recent advance being the adoption of the Holby milk ordinance which is modeled after the U. S. Public Health Service standard milk ordinance.

Almost 40 years ago when the late Miss Adams and the agricultural college were pioneering for an improvement of Chicago's milk supply, the chief concern was the matter of "watering," or diluting milk.

The college's first work with the Chicago milk market, in which the late Miss Adams figured, has been followed by other studies and investigations, all of which have played a prominent part in establishing the high standards of the present day, Prof. Tracy said.

Chopping Hay May End This Season's Haymaking Warnings

With a record dry season in prospect, Illinois farmers are looking ahead for means of reducing hay storage losses to make room for the expected hay crop as well as for the additional hay from the beams. Hay chopping is a practical way of reducing the barn room needed for storing livestock feed, according to F. H. Bond of the agricultural engineering department, College of Agriculture, University of Illinois.

Chopped hay may be stored from one-half to two-thirds less barn space than long hay. This extra room may be used for other purposes if the barn is strong enough to carry the added weight. Not only does chopping the hay waste less available space for the storage of other feeds, but also waste is reduced, Bond said. With long hay, farmers have shown that as much as 30 per cent may be lost. With chopped hay stored, waste may be reduced to a maximum of 5 per cent.

Convenience during the winter feeding season is another advantage of chopped hay. It is easier to pitch down from the mow than long, baled hay. Since chopped hay has less cull, a day's supply or more can be placed in the feeding racks or hangars at one time.

The cost and speed with which hay can be stored by chopping varies with the individual farm. Where a hay chopper with adequate feeding mechanism is available, the hay can be put into the mow faster than by other methods. An ordinary hand cutter does not speed up the process, Bond said. With the equipment available on most farms, the cost of storing chopped hay is about the same as for long hay.

Breeding Tests With Antichlorals With Artificially

Artichlorals which the American artichloral pills as a new one for Illinois farmers are expected to be used in the experiments which the College of Agriculture, University of Illinois is now conducting on improved methods of propagating the plants.

While the artichloral has no facilities for the lay stock farmer as a cash crop for farmers in this state, it has not been introduced except in experimental plots and, to a very limited extent, in terms, according to C. A. Wright, chief of the college plant genetics division.

One source that the plant is being used in the experiments at the college has been conducting during the past three years in the discovery that self-fertilization is an ineffective way of propagating the plants. Since artichloral is self-fertile, the resulting seedlings vary and the result, under conditions, wilder perfection, leaf blight, resistance to frost, etc., etc., and the plants are very different. These are wanted from the plant, however, the plant is very different.

This discovery has opened the possibility of developing a new type of plant by crossing desirable self-fertile plants and crossing them with those obtained from the same hybrid. While a source has been produced during the past, the tests are being continued in spring with the hope of producing better seedling plants, Wright stated.

The artichloral is a good plant for use, cattle and other livestock, it has been demonstrated by experiments. In addition its value as a human food has been proved. Not only can the plant be used as a vegetable but it is also a source of vegetable oil, both for use and for use.

Let those who are interested in the artichloral, the latter representative the cane sugar for animal fruits and is a very excellent product. However, sugar is needed. Sprays, prepared at the college, are considered a very good quality by those who taste it.

Apple Is The Best Fruit For C. W. Wright And A. L. H. H. H.

This is the year to hold the planting with a good to buy, said U. W. Wright, horticultural extension specialist at the College of Agriculture, University of Illinois. Cooling with, which have caused Illinois to lose up to the extent of a million dollars each year, were defeated in 1944 by wet, hot weather and effective spraying. They will be lost in the next few years by effective spraying or they will reproduce and return with a vengeance.

Like any other fruit, the spraying must be done thoroughly this summer so that every possible insect of the kind will be removed by the spraying. In addition the entire surface of every apple must be covered with the spray if the fruit is to be protected.

The cooling with larvae has no preference to cause. It is just as likely to enter the apple from the side toward the center of the tree as from the outside. Consequently, it is necessary to cover the entire surface of the fruit. This can be done only by the use of proper sprays and in the case of the apple, the problem and the consistency in their efforts to control the disease, H. H. H. stated.

After the spray has dried, any spots that have been observed on the apple. By climbing the tree, the orchardist can inspect the surface of the fruit and the center as well as the top part of the tree. Finding the insects, etc., and giving trees a dose of the spray will go a long way toward assuring the production of well-ripened apples this year.

With large trees the spray should be applied both from the inside and the outside.

## July, with Spring six A

July, 1914, was a very dry month in Illinois, with the heaviest rain falling on July 15th. The total rainfall for the month was 1.5 inches, which is very low for this time of year. The temperature was generally high, with a maximum of 90 degrees on July 15th. The humidity was also high, with a relative humidity of 75% on July 15th. The wind was generally light, with a maximum of 10 miles per hour on July 15th. The overall weather was very hot and dry, which is not ideal for the growth of crops.

July 15th, 1914, was a very hot day in Illinois, with a maximum temperature of 90 degrees. The humidity was also high, with a relative humidity of 75%. The wind was generally light, with a maximum of 10 miles per hour. The overall weather was very hot and dry, which is not ideal for the growth of crops. The soil was very dry, and the plants were showing signs of stress. The farmers were concerned about the impact of the dry weather on their crops.

July 16th, 1914, was a very hot day in Illinois, with a maximum temperature of 90 degrees. The humidity was also high, with a relative humidity of 75%. The wind was generally light, with a maximum of 10 miles per hour. The overall weather was very hot and dry, which is not ideal for the growth of crops. The soil was very dry, and the plants were showing signs of stress. The farmers were concerned about the impact of the dry weather on their crops.

July 17th, 1914, was a very hot day in Illinois, with a maximum temperature of 90 degrees. The humidity was also high, with a relative humidity of 75%. The wind was generally light, with a maximum of 10 miles per hour. The overall weather was very hot and dry, which is not ideal for the growth of crops. The soil was very dry, and the plants were showing signs of stress. The farmers were concerned about the impact of the dry weather on their crops.

## Eradication of Mole's Will Destroy Comeback of Lemms

The lack of rains and hot days after the month of June will be sustained if mole's are eradicated, said G. C. Berkirk, Chief of U. S. Biological Survey, who is cooperating with the College of Agriculture, and the Illinois State Game and Fishery Survey.

While various preparations will be made to get rid of mole's away from the garden and lawn, trapping is the most effective method of getting rid of mole's, other than poisoning. The traps should be located along the main burrows or those which appear to be newly made. The traps should be reset frequently, especially in the early morning and late afternoon when the mole is most active. The choker and scissor type traps are the most efficient, although the cone type is satisfactory if it is firmly secured in the soil and the trigger is set in contact with the snout of the mole. In setting any type of trap, the operator should first step lightly on the surface of the ground and then locate the trap with the trigger in close contact with the soil, Berkirk said.

Bang's Disease "Cure" Getting Clean Litter Back

Clean litters have had their day, but take care for Bang's disease. If cattle are still being sold to farmers for \$5 to \$8 a head, according to Dr. Robert Graham, chief in animal pathology and hygiene, at the College of Agriculture, University of Illinois.

Just as there is no sure "antirabic" serum, there is no cure for the costly Bang's disease, and it is not a cure, but by getting litters clean, Dr. Graham said.

The typical "antirabic" serum is a colorless liquid which is found to be ordinary corn starch with just enough potassium permanganate added to make a pink solution in water. A pound of this combination costs only a few cents, yet the manufacturer was selling it to farmers at first for \$15 per gallon, rising from a pound to a pound and a half. It is now being sold at a prohibitive but the price was badly wasted, Dr. Graham stated. Pink cornstarch will not cure Bang's disease, but at \$5 to \$15 a gallon will keep litters clean.

Since Bang's disease has been reported to have spread from one farm to another, farmers are willing to try some "antirabic" serum, and to eliminate the disease from the herd. Some evidence is given to these claims by the fact that some cows develop a resistance to the disease, and the animals are cured. Often the usual remedy is given credit for this natural cure.

Even though the symptoms are gone, the animal retains the disease and is capable of spreading it to the rest of the herd. Only by finding the source and eliminating them from the herd can the farmer win a free of Bang's disease, Dr. Graham explained.

For details on Bang's disease tests, litters should be examined with a test of formalin solution. If the litters are clean, it is a cure. At the present time the Federal Government is carrying on a campaign to clean up litters in Illinois and other states with a view to owners for cattle being sold from the herd. In addition, the college is carrying on a project which for several years has been giving farmers a chance to test their litters and eliminate bacteria.

Freezer Cooker A. Edwards, Not An Expensive Appliance

Far from being an expensive luxury, the freezer-cooker will be an economical Illinois housewife who also has to take next winter's food bills by canning fruit and vegetables this summer, says Miss Anne A. Henderson, food nutrition specialist at the College of Agriculture, University of Illinois.

Freezer-cookers can be bought for as low as \$8 although the average price ranges from \$15 to \$25. Extending a cooker, a woman can still be able to provide the family with soft-canned foods and also save at college, especially of the non-acid vegetables and meats, thus saving many times the cost of this class of products. Since there is practically nothing to wear out, the equipment will last for years.

The freezer-cooker operates on the simple principle of increasing the air pressure. With the set-out relation to air, the temperature never goes higher than 100 degrees Fahrenheit at sea level. With the cooker, however, much higher temperatures can be reached and cause the sterilization of food.

Non-acid vegetables may spoil in the ordinary refrigerator, but the high temperature possible only in the freezer-cooker. In fact, the high temperature is accompanied by the formation of clostridium botulinum, a dangerous bacterial organism. While it may be recovered in the freezer-cooker, the high temperatures are not necessary for the successful cooking of these foods.

Dr. R. H. Gray, Georgia Institute of Technology

Dr. R. H. Gray, Georgia Institute of Technology, has been elected to the position of President of the American Association of Economic Geologists. He is the first American to hold this position. He was elected at the annual meeting of the association in London, England, in 1928. Dr. Gray is a member of the National Academy of Sciences and the American Philosophical Society. He has published numerous papers on economic geology and is the author of the book "Economic Geology" published in 1927.

Dr. Gray's researches have been primarily in the field of the geology of the Southeastern United States. He has been particularly interested in the geology of the Appalachian region. He has published many papers on the geology of this region and has been instrumental in the discovery of many new mineral deposits. He is also interested in the geology of the world and has published many papers on the geology of other countries. He is a member of the American Association of Economic Geologists and has been elected to the position of President of this association.

He was elected at the annual meeting of the association in London, England, in 1928. Dr. Gray is a member of the National Academy of Sciences and the American Philosophical Society. He has published numerous papers on economic geology and is the author of the book "Economic Geology" published in 1927.

Dr. Gray's researches have been primarily in the field of the geology of the Southeastern United States. He has been particularly interested in the geology of the Appalachian region. He has published many papers on the geology of this region and has been instrumental in the discovery of many new mineral deposits. He is also interested in the geology of the world and has published many papers on the geology of other countries. He is a member of the American Association of Economic Geologists and has been elected to the position of President of this association.

Although the term "economic geology" is often used to describe the study of the earth's resources, it is a very broad term. It includes the study of the distribution and use of minerals, the geology of the world, and the geology of the Southeastern United States. Dr. Gray's researches have been primarily in the field of the geology of the Southeastern United States. He has been particularly interested in the geology of the Appalachian region. He has published many papers on the geology of this region and has been instrumental in the discovery of many new mineral deposits. He is also interested in the geology of the world and has published many papers on the geology of other countries. He is a member of the American Association of Economic Geologists and has been elected to the position of President of this association.

The work of Dr. Gray and other geologists has been of great value to the world. They have discovered many new mineral deposits and have helped to develop the geology of the world. They have also helped to develop the geology of the Southeastern United States. Their work has been of great value to the world and has helped to develop the geology of the world.

Dr. Gray's researches have been of great value to the world. They have discovered many new mineral deposits and have helped to develop the geology of the world. ## How to Deal with the Hogs That Carry Swine Fever

Swine fever is a very infectious disease, or infectious abortion, with a very high mortality. It is a disease which the Illinois Department of Agriculture has just assumed to help farmers or county agents deal with in their districts. The disease is called "Swine fever in hogs," and is caused by the Robert Gray virus which pathologists have shown, and which is a small, round, virus particle.

Twenty-six counties in the State have had four or more different counties of the State during the past year or more, but only one county has had a definite case of the disease, the other counties having had only a few cases of the disease.

Only one county in the State has had a definite case of the disease in a county during the past year or more, but only one county has had a definite case of the disease.

The disease is spread by the herd without the disease being in a cause infected sows or sows that are infected and show no signs of harboring the malady. On the other hand, a sow may lose her milk, but she does not necessarily show any signs of infection. It is a very infectious disease and can be spread by a herd actively infected herd, but it is not a disease of a herd and it is hard to herd. The disease is spread by contact with infected sows and water and from infected hogs at or during the breeding season.

No doubt, the facts are available for ascertaining whether or not hogs are infected with the disease. The blood agglutination test, if positive, is a definite indication that the animal has the disease. Even more definite is the finding of the virus organisms causing the disease. This is accomplished through microscopic examination of the virus particles.

The Illinois Department of Agriculture has been having their laboratories, both in the State and in the United States, and has been having their laboratories in the State and in the United States, and has been having their laboratories in the State and in the United States.

Along with the virus and infection of the disease, the virus, being highly infectious, can be readily spread and is a very infectious disease.

The disease is a very infectious disease and is a very infectious disease. It is a very infectious disease and is a very infectious disease.

Structure and Life of Burr Berries for Red and Yellow

In the Florida Department of Agriculture, the following specimens of yellow and red berries sent to the College of Agriculture, University of Illinois, for study. The specimens are so badly damaged in this case that they are identical with those possibly belonging to W. T. Flint, chief entomologist of the college. Entomologist, Florida Department of Agriculture, History Bureau.

The danger of the disease is that the berries are so badly damaged that in some parts of the structure the disease is so advanced that the structure is almost entirely destroyed and the berries are so badly damaged that they are almost entirely destroyed.

There are several specimens of yellow and red berries from Florida, all of which have at least one or two specimens of the disease. The specimens are all of the same variety and are all of the same variety. The specimens are all of the same variety and are all of the same variety. The specimens are all of the same variety and are all of the same variety.

The structure of the berries is so advanced that the structure is almost entirely destroyed and the berries are so badly damaged that they are almost entirely destroyed. The structure of the berries is so advanced that the structure is almost entirely destroyed and the berries are so badly damaged that they are almost entirely destroyed.

One of the specimens of the disease is a specimen of the disease. The specimen is a specimen of the disease. The specimen is a specimen of the disease. The specimen is a specimen of the disease.

Another specimen of the disease is a specimen of the disease. The specimen is a specimen of the disease. The specimen is a specimen of the disease. The specimen is a specimen of the disease.

Whether the disease is a specimen of the disease. The specimen is a specimen of the disease. The specimen is a specimen of the disease. The specimen is a specimen of the disease.

Rustlers Don't Crow About Egg Loss Of Five Counties

Rustlers have nothing to crow about in the matter of egg loss in five counties. A loss of from \$100 to \$400 is being suffered by some of the small farmers who are taken out to prevent the egg thieves. I. H. Ripley, county commissioner of the village of Appleton, Illinois, says that the loss of fertile eggs that spoil or get washed away is not so great as it is reported to be. He said prices. It represents a loss of about \$100 to \$200 for the farmer, he said.

The direct loss of \$100 to \$400 is not so great as it is reported to be through fertile eggs that spoil or get washed away. I. H. Ripley, county commissioner of the village of Appleton, Illinois, says that the loss of fertile eggs that spoil or get washed away is not so great as it is reported to be. He said prices. It represents a loss of about \$100 to \$200 for the farmer, he said.

## High-Grade Farm Land Shows Increase in Value

With the recent gain in farm income in Illinois, high-grade farm land is getting the price which it merits. From a report by C. C. Stewart, chief in land valuation at the College of Agriculture, University of Illinois.

High-grade land has shown an average of between 10 and 17 per cent increase since 1914 as compared to 1913. The increase in the low and poor grades. With a large share of the high-grade land sold in the west part of Illinois, farmers in that section were favored with greater real estate increases. These were those in the poor-land sections, mostly in the east part, the mid-grade in the western sections.

The widening of the gap between high and low prices of land is the reverse of what happened in Illinois and other states between 1911 and 1914. The price of farm land was falling. The widening was caused by a number of causes in good and poor land.

Approximately 70 per cent of the farm land in Illinois is rated as top rate, compared to 50 per cent in the average of all states in the United States. The second, third and fourth grades are about 20, 10 and 10 per cent each, while the fifth, sixth and seventh grades are about 10, 10 and 10 per cent in Illinois.

Farm valuation statistics for 1917 and 1918 are as follows: Grade in the following proportion: first grade, 70 per cent; second, 20 per cent; third, 10 per cent; fourth, 10 per cent; and fifth, 10 per cent. Only Iowa rates the first grade with a larger percentage of grade 1 land than Illinois.

With the increase in farm land prices in Illinois, the price of land in relation to the price received for crops by farmers, which has been the case in recent years has lightened the farm burden. In fact, this may have had the influence in increasing farm land values. The increased prices for crops, Stewart believes,

## Wasting Of Limbs is Caused By Anthracnose Damage

Spitting, withering and falling of leaves from oaks, elms and maple trees that is now causing so much concern in the work of the anthracnose disease, says Dr. J. A. Fenck, consultant of the Illinois Cattle Path and History Survey, cooperating with the College of Agriculture, University of Illinois.

A most complete prevention of anthracnose can be obtained by spraying susceptible kinds of trees with a bordeaux mixture. The first spray should be applied while the leaves are unfolding. If wet weather continues, the spray must be repeated at intervals of about ten days or more to prevent the occurrence of new infections. Even if the first spray is missed, most of the infection can be prevented and the majority of shade trees largely preserved by beginning to spray as soon as anthracnose infection is observed. Trees that have suffered severely can often be induced to make good growth if they are supplied with nitrogenous fertilizers.

An epidemic of the disease is always to be expected in wet cool springs. As rule trees suffer very little permanent damage from the anthracnose attack.

-M-

Insects Brighton Chances For Seed Crop Off Clover

This may be one of those rare years when insects will come to the aid of farmers and give them the benefit of a cash seed crop from the first cutting of red clover, according to W. P. Flint, chief entomologist of the Illinois State Natural History Survey and of the College of Agriculture, University of Illinois.

In answer to numerous inquiries, he is recommending that farmers let the first crop of red clover stand for seed if enough heads have bloomed to produce a profitable crop of seed. However, if heads are so scarce that only a light seed crop can be expected, farmers may as well follow the usual practice of cutting the first crop for hay and letting the second crop stand for seed, he said.

Shortages of clover seed following the 1933 drought and the increasing acreages of legumes throughout the United States have combined to put a premium on the production of seed crops, it was pointed out. Success of the clover seed crop, however, depends largely upon the presence of certain insects that pollinate the seed heads, Flint said.

This year it just so happens that there are rather large numbers of clover pollinators present. Farmers can expect a good cut of seed in the heads that bloom for the first crop. Ordinarily only the second crop of clover is used for seed, because by that time there are usually enough bumble bees to insure a good cut of seed, although this seed may later be destroyed by other insects.

The chief threat to a good first-crop clover this year is the clover bud weevil. It has destroyed so many of the clover buds that it is doubtful if enough heads will form in many fields to make a profitable seed crop in the first cutting.

Any seed that the farmer can get from the first crop undoubtedly will be worth saving, inasmuch as there are several seed-destroying insects that are fairly abundant this year and that are likely to cause more or less injury to second-crop seed, Flint said.

-M-

Danger Of Deadly "Salk" Disease Still In Sil Corn

With sporadic outbreaks of the so-called cornstalk disease still occurring in Illinois, farmers can not afford to take chances feeding either grain or fodder of the 1934 crop to their horses, said Dr. Robert Graham, chief in animal pathology and hygiene at the College of Agriculture, University of Illinois.

The outbreak which was at its peak during the past winter is estimated to have caused a loss of nearly half a million dollars among farmers in the central sections of the state. Estimated loss during the winter period amounted to approximately 7,000 horses.

No definite conclusions have been reached as to whether the grain or the fodder has been the cause of the trouble. The disease was reproduced experimentally by placing horses in a 55-acre corn field in Champaign County during the winter. Confirming observations by veterinarians and stockmen indicated that droughted corn, such as that grown during the drought of 1934 may, in some way, be responsible for losses of horses from the disease.

Old corn has been fed with safety to hogs and cattle on the same farm when the horses died.

Since there is a strong indication that the 1934 corn is at the root of the trouble, oats should be used as a horse feed until a new corn crop is available, according to Dr. Graham.

Early treatment of the diseased horse by a local veterinarian will often result in a cure. The first symptoms are sluggishness, staggy gait and evidence of sleepiness and blindness. When any of these first symptoms appear, the veterinarian should be called. After the horse goes down and is unable to rise, death usually follows.

## Drouth Broken but Bugs Still Cost Growers Millions

While Illinois gardens are not being ruined by drouth this year, gardeners and vegetable growers still stand to lose between four and five million dollars from insects if the season is average. This is pointed out in a new circular, "Saving Garden Crops From Insect Injury," which has just been published by the College of Agriculture, University of Illinois.

Insecticides are essential in the control of injurious insects, but cultural practices are also of great benefit in reducing the damage, according to the circular, which was prepared by L. H. Shropshire, field entomologist, and C. C. Compton, associate entomologist, Illinois State Natural History Survey, who are cooperating with the college.

Some 54 insects which commonly attack garden plants are listed in the circular. A description of each insect, its habits, method of injury, life history and the best means of control is given. Illustrations are included to help gardeners recognize the various kinds of injurious bugs.

Insects attacking each of the major vegetable and fruit crops are grouped separately and control measures outlined for each of them. There are separate sections for insects attacking cabbage and related crops, potatoes, sweet corn, tomatoes and eggplant, vine crops, celery, peas and beans, asparagus, cress, spinach, lettuce, celery and dill; carrots and radishes, horse radish and sweet potatoes.

With insecticides playing an important part in the control of garden insects, the circular explains the composition, the kinds of insects against which each type of poison is effective and the precautions which must be observed in handling the insecticides. Arsenate of lead and the silicates are not recommended for plants where the treated portions will serve for food, since there is slight danger of poisoning.

The two general types of insecticides, stomach and contact poisons, are described in the circular and directions given for mixing, applying and handling them.

## Safety In Home Would Reduce Bill Of 600 Millions

With home injuries costing people of the country 600 million dollars a year, the Fourth of July is a good time to start an intensive safety campaign in every Illinois home, in the opinion of Miss Gladys J. Ward, home management specialist at the College of Agriculture, University of Illinois.

Home accidents seem to be getting more dangerous instead of less on the basis of the evidence that there were 3,400 more fatalities from home accidents in 1934 than there were in 1933, she said. The total for the past year, according to figures from the National Safety Council, was 38,000, the largest since the council started making estimates of home injuries and deaths.

The estimated total of both fatal and non-fatal injuries in the home during the past year was 4,000,000. The cost of these injuries, including wage loss, medical care and overhead expense of insurance amounted to 600 million dollars.

Thrashing Season Is Welcome Relief To Stock Feeders

Opening of the thrashing season in Illinois is more welcome than ever this year, for it means the end of a rough feed shortage for stockmen who have been forced to buy corn, said E. T. Robbins, livestock extension specialist at the College of Agriculture, University of Illinois.

When corn is worth \$1 a bushel, wheat is worth a dollar for general feeding purposes, rye 90 cents, barley 75 cents and oats 50 cents. This difference between the price of corn and of small grains allows for the grinding of small grains in most cases. The best results are usually obtained when the small grain is coarsely ground, Robbins stated.

For fattening cattle not more than half of the ration should be composed of any one small grain. Equal parts of wheat and oats form a satisfactory cattle fattening ration, especially when supplemented with an pound of cotton seed meal to each seven pounds of grain long with a few hay.

Such a ration has been fed to steers at the college with good results. The steers averaged 1.36 pound of gain daily for three months. At that time corn was 77 cents a bushel, wheat 70 cents and oats 50 cents. A greater profit was returned on this ration than when corn or other grain combinations were used with the same supplements.

Pigs growing and fattening on pasture do well even though wheat replaces all of the corn in the ration. A ration of half wheat and half grass, fresh chisel, and pasture has also shown good results. The addition of a small amount of whole oats or up to one-third of the grain content in ground oats improved the ration.

Guernsey Field Day Is Set For July 11 Near Wheaton

Recent encouraging returns in the dairy industry are expected to help swell the turnout of Guernsey cattle breeders for the annual field day of the Illinois Guernsey Cattle Breeders' Association which will be held on the St. James Farm, near Wheaton, on July 13.

Approximately 50 probably will attend, according to those in charge of the program. Prof. J. S. Rhoda, of the dairy department, College of Agriculture, University of Illinois, will be master of ceremonies for the day's program, and E. I. Pilchard, boys' 4-H club specialist of the college, will be in charge of a Guernsey judging contest open to teams of 4-H club members from any part of the state.

In addition to the contest other features of the program will include an inspection of the St. James herd, which is one of the best representatives of the Guernsey breed in the state. Outstanding animals as well as methods of feeding, breeding, and managing the herd will be attractions.

L. R. McNeil, Tuscola, is president of the Illinois Guernsey Cattle Breeders' Association, which is arranging the field day. H. C. Hermanson, Danville, is secretary-treasurer, and directors are F. W. Winker, Belleville, R. E. Michelroy, Carbondale, and I. C. Studer, Reanoke.

Plans for the meeting have the advantage of being laid at a time when Guernsey breeders and other dairymen are taking stock of a number of encouraging features in the industry. Prices of dairy products are markedly higher than they were last year, and with the short storage stocks and a fairly steady demand could maintain a reasonably firm position, economists believe. Pasture is such a crop as ever what it was a year ago, thereby easing the feed situation, while butter exports, which amounted to 10 million pounds during the first five months of the year, have largely ceased owing to the disappearance of the export margin between New York and London prices.

-1-

Farmers Are Out To Save Timothy And Red Clover Seed

With supplies of red clover and timothy seed such smaller than usual and some of such seed being used for soil conservation and crop adjustment purposes, there will be an added premium on all the red clover and timothy seed that Illinois farmers can manage to save this season. This opinion of C. C. Pieper, chief production specialist of the College of Agriculture, University of Illinois.

Fortunately, another source of planting incidents will be present this year to produce seed in the first cutting of red clover. Ordinarily, however, the first crop is cut for hay and the field then left for a second crop. The amount of seed produced by this second crop depends largely upon bees. Since the pollen of red clover is heavy and sticky the crop will not fertilize unless bees or other insects scatter the pollen. Bumble bees, the large white bees and the white-crowned sparrow hawk are the best carriers of pollen.

Red clover should be cut when the first tips are green, says Pieper. If the crop is cut too early, the seed will not be ready for putting down that a lot of the seed will be wasted by chattering.

While there is nothing of a real shortage of timothy seed, the supply of seed will be the easiest to make up, says Pieper. A large number of soft seed as well as recently saved alfalfa and other large-crop seeds will be ready for use. Consequently, enough timothy should be left in the field at least the farmers who need it for seed next year.

The best time to harvest timothy seed is when most of the heads have turned brown and the seed is just beginning to shatter from the center tip of a small portion of the earliest heads.

Heavy Rain, Snow Yield Of Efficient Water Equipment

Heavy rains in Illinois during the past few weeks have emphasized the need for proper construction of late fall water equipment. When the ground becomes mud holes filled with dirty, unpalatable water will be a serious matter to livestock health, said W. A. Foster, rural architect of the College of Agriculture, University of Illinois.

Keeping plenty of clean, fresh water in every pasture and feed lot is a basic principle of good livestock management and one practical safeguard against spread of disease. The supply may come from a well, spring or stream, but the actual watering place should be so constructed as to protect the water from contamination.

Where the source of the water is a pond, the water will recede as the dry season of the year approaches. This will necessitate the livestock wading knee-deep through mud to reach the stagnant, impure water unless special provisions are made to avoid this.

One of the best watering systems for a permanent pasture can be made by building a short concrete trough in a spring run and providing a concrete approach. This arrangement makes the water easily accessible for the herd and does away with the mud hole menace.

Watering places which prevent contamination, for example, 2 1/2 inches diameter of water are not only useful during wet seasons when the water is abundant but are also well worth the money during dry seasons such as the summer of 1934.

Where plenty of gravel or stone is available, it may be these materials may be substituted for concrete in the construction of a trough. However, where mud should be avoided, since they dry in mud and dirt.

## Welcome Farmers' Destructive Millions Through Soil Erosion

Welcome as they have been, record rains throughout Illinois this spring have cost farmers millions of dollars in soil erosion and left damage which will take years to repair, it is estimated by Dr. T. L. Burlison, head of the Department of Agronomy and chairman of the soil conservation committee, College of Agriculture, University of Illinois.

Fortunately, farmers and the general public have been so struck by the damage that there is now a more concerted effort being made to halt erosion and keep farm lands and valuable soil fertility at home, he said.

Streams and rivers filled with muddy water, fish restricted with newly formed gullets, gullies that have widened and deepened and ditches that have been silted full or partly full have all served to bring home the wreckage of damage which erosion has done to unprotected fields, according to Dr. Burlison.

In May alone almost double the normal amount of rainfall was reported by 101 weather stations of the state, Dr. Burlison said. The average was 7.73 inches, whereas the normal amount is 4.1 inches. Flood damage has been reported in 7 of the 10 counties of the state.

Erosion this spring was measured as three million acres of Illinois land that should never be farmed, or 100,000 acres less covered with other tillable acres that are subject to serious erosion and that are suitable only for orcharding, permanent pasture or timber. There is an additional area of more than 2, 10,000 acres in the state where erosion lowered the productivity of the land unless it was protected, and little of it was, he said. Soil washing even added to its toll in 10,000,000 acres of relatively flat land in the state where erosion occurs on the steeper slopes.

Erosion was all the worse during the heavy rains because of the water effects of the 1934 dry weather, Dr. Burlison pointed out. In many fields the earth was dry and powdery when the heavy rains came, and tons of valuable top soil went down rivers and streams to make them still muddier than they already were, he said. With the top soil washed away, valuable fertility elements were lost and the raw subsoil was brought nearer the surface. Once erosion has advanced to the place where the subsoil is exposed, Nature can build it into tillable top soil only after thousands of years, Dr. Burlison said.

The fact that many fields also were stripped of vegetation is a result of the 1934 drouth made erosion losses heavier this year, Dr. Burlison said.

Seriousness of soil erosion this spring has given new impetus to the work which the College of Agriculture, University of Illinois has been carrying on for years to help farmers cope with this problem. One of the most recent developments in this work has been the inauguration by Dean H. J. McLeod of the state coordinated soil conservation and improvement project which brings together the forces of all agencies now active in this field.

Improving Soil of Farm Land in South West Ohio

A little special equipment and a lot of patience are the only requisites for a farmer to overcome acid soil and make his land more productive. The soil of Ohio, especially in the western part of the State, is generally acid. This is due to the fact that heavy rains have washed away the lime and other minerals which are naturally found in the soil.

Soil that is acid will usually grow only a few crops. The farmer who has such a field problem for the first time will usually get a good crop of corn and a few other crops. The soil is so acid, however, that it will not grow a good crop of wheat, clover or alfalfa. The farmer who has such a field problem for the first time will usually get a good crop of corn and a few other crops. The soil is so acid, however, that it will not grow a good crop of wheat, clover or alfalfa.

The only satisfactory method of soil correction is the use of a well graded engine attached to the end of a plow, for cutting and binding. The use of the machine, Young's system.

Log and sawdust are good for soil correction, said Young. Extension guards attached to the regular engine will do the work of sawdust. The use of the straightening the stream. Young's method is to use a well graded engine for the work of the soil. If the grain is heavy, it may be necessary to cut and bind in the direction, that is opposite the way the grain is cut.

Cutting with a well graded engine is a satisfactory method of soil correction. The use of a well graded engine for soil correction is a satisfactory method of soil correction. The use of a well graded engine for soil correction is a satisfactory method of soil correction.

During rainy seasons, when the soil is so acid, it is advisable to use a well graded engine for soil correction. The use of a well graded engine for soil correction is a satisfactory method of soil correction. The use of a well graded engine for soil correction is a satisfactory method of soil correction.

Fireworks Insect Warfare Between Fox Creek Livestock

Fourth of July, with all its usual fireworks, promises to be a beautiful firework display, in fact, but the real fireworks for the Fourth of July may be the war of insects, said Dr. F. W. Bell, director of the Ohio Agricultural Experiment Station, Columbus, Ohio.

Most varieties of insects are active during the summer months, and the war between them is a constant one. The main war is between the locusts and the grasshoppers. The locusts are the most destructive of the insects. They are found in the western part of the State, and they are the most destructive of the insects. They are found in the western part of the State, and they are the most destructive of the insects.

Good Pastures Do Not End Risk Of Snakeroot Poisoning

Heavy rains which have made Illinois pasture luxuriant this year have not ended the danger of white snakeroot poisoning to man and to livestock. Being in full bloom in a few months, according to a warning in a newly revised circular, "White Snakeroot Poisoning," which has just been issued by the College of Agriculture, University of Illinois.

Even though pasture grass is abundant, animals may eat the leaves of the poisonous white snakeroot weed from time to time. Overstocking pastures, even if they are good ones, increases the risks from the poisoning, which occurs every year in Illinois, the circular warns.

Persons using dairy products or meat of animals affected by "trembles," as white snakeroot poisoning is known, may contract milk sickness, an ailment which runs a rapid course and has a high mortality rate.

Keeping livestock away from white snakeroot and eradicating the weed from pastures and woodlots are the only sure ways of preventing the poisoning, according to the circular. Treatments for the disease are of a very unsatisfactory nature. The toxic agent in the plant and is absorbed into the animal's system when the plant is eaten, according to the circular, which was written by Dr. Robert Grace, chief in animal pathology and hygiene at the college, and his assistant, Miss V. M. Michael.

The plant is a tall, slender annual herb which usually grows in partially cleared woodlots, swampy areas, shady ravines and in groves along streams. The greatest danger is from July until late in the fall. This is especially true during dry years when pastures are short and dry. White snakeroot can generally be recognized by its broadly oval leaves, set opposite each other and having sharply-toothed, or serrated, edges. The non-poisonous varieties usually have narrower leaves.

In small patches the weed is best eradicated by pulling each plant by the roots. In large patches proper spraying is the most satisfactory means of eradication. Livestock should be kept out of pastures containing any of the weed.

Weakness, loss of appetite, constipation and a trembling of the voluntary muscles when the animal is forced to move are among the early symptoms of poisoning. When these symptoms are observed the stock should be taken from pasture and a reliable veterinarian called. The immediate attention of a physician should be given to cases of milk sickness among humans.

-4-

Chinese Elm Is Not As Slightly Shaded Tree As Believed

A new threat to shade trees in the form of a trunk canker affecting Chinese elms has just been found in Illinois, while a root rot has been reported attacking this particular type of elm throughout the Great Plains region, according to Dr. J. C. Carter, tree disease specialist with the Illinois State Natural History Survey, who is cooperating with the College of Agriculture, University of Illinois.

These developments are a warning, he said, that persons who plant Chinese or other Asiatic elms in place of the American elm may be disappointed if they expect these new varieties to be entirely free from disease attack.

The Chinese and other Asiatic elms, which are resistant to the Dutch elm disease, are susceptible not only to the two recently reported diseases but also to several others. Among the more common diseases which afflict Chinese elms are stem and basal trunk cankers and a number of leaf spotting diseases.

## Chinch Bugs Are In All But A Few Scattered Areas

Chinch bugs have now been nearly wiped out in Illinois for this season and probably will not recover from the setback for four or five years, according to W. J. Flint, chief entomologist of the Illinois State Natural History Survey and of the College of Agriculture, University of Illinois.

Except in a very few scattered areas over the state there are not many chinch bugs left, he reported.

By putting an end to the farmers' chinch bug worries for this year, the heavy rains which came just at the right time have been worth more than 4 million dollars to Illinois grain growers for this year alone, Flint said. Damage to this amount was done to the state's corn, wheat and oats by the 1934 infestation, and if the weather had not been unfavorable to the pests, the toll this year probably would have been even longer, he said. Illinois had begun the season in the last winter to start the new infestation, which was the case in 1934, he pointed out.

Only in a few scattered places in the state are the bugs thick enough to make it worth while for farmers to build barriers for protecting corn fields against the migration of the pests from small grain fields at harvest time, Flint said.

Farmers of the state last year built the two 22,000 miles of musquito carriers, without which the 4 million dollar toll taken by the bugs would have been even higher.

There could be no more striking demonstration that the weather is the most important factor in the control of chinch bugs than has taken place this year, Flint pointed out. Cool weather early in the season kept the old bugs in winter quarters and thus delayed their summer laying. Later the heavy rains browned the old bugs and beat the young ones into the ground where they were "killed" in and died. Dampness and high humidity were favorable to the spread of the white fungus disease which attacks the bugs.

The few bugs that were produced and survived from the first brood are now in cornfields or soon will be, Flint said. If they have not already done so, they will very shortly grow wings. There will then be a general flight and the bugs will scatter over the cornfields, usually seeking the thinner stands of corn in order to avoid dappled and shaded areas.

During the next three months the bugs from the first brood will remain in the corn. During this time a second brood will be produced.

Wet weather in August will greatly reduce the second brood and thereby lessen the danger of damage next year, Flint pointed out.

Any bugs that survive from the second brood will start their flight from the cornfields to winter quarters about the last of August. The movement will be completed by the first of November or earlier.

More Seeding Of Alfalfa Likely On Illinois Farms

There will be a wave of new plantings of alfalfa and similar crops in Illinois this fall, and many farmers already are laying their plans for seed bed preparation, according to J. C. Hackleman, crops extension specialist of the College of Agriculture, University of Illinois.

Hay shortages resulting from the 1934 drought, as well as the loss of alfalfa seedlings from late cutting last fall and from ice sheets in the winter, have made new plantings more urgent this year, he said.

In the northern sections of Illinois alfalfa does best if seeded between July 30 and August 1. In the central and southern sections August 1 to 15 is the best period, Hackleman stated. This means that seed bed preparation must begin immediately after the small grain has been removed from the field.

Proper seed bed preparation is one of the most important factors in the successful raising of alfalfa, Hackleman believes. The ground should be well pulverized, firm and settled. It neither will be nor sweet clover has been grown in the field before, in a rotation, a necessity. All soils should be tested for acidity before being seeded to alfalfa. Where limestone is needed, the material should be worked into the soil late this summer and then over the alfalfa seed spring. This method will give the limestone plenty of time to sweeten the soil.

In choosing seed the farmer should consider soil fertility, normal climatic conditions, and the possibility of bacterial wilt. Variegated varieties such as Hardigan, Prim and Canadian variegated are generally better adapted to the northern sections of Illinois, since they are extremely resistant to wilt. However, they are short-lived in the face of wilt. Where bacterial wilt is known to be in the soil, a good quality western variety such as Bluebird may last for two years, which is the average length of life for alfalfa in wilt-infected soil, regardless of the variety.

Where the winters are not too severe, the northwestern colored alfalfas grown in Montana and the Dakotas, as well as Nebraska and Yankee cow peas, will be satisfactory.

With the exception of Hardigan seed which is limited, seed of most of the varieties can be obtained without difficulty. However, growers should obtain seed of known origin and quality, preferably that which has been certified, Hackleman stated.

Twelve to 15 pounds of seed to the acre is the best sowing rate for Illinois conditions. This is on the basis of good quality seed having a high germination fact.

-1-

Good Cows Crop Will Help Feed Farm Warrives For Hogs

Prospects for a better than average cows crop as the harvest season opens are more cheering than ever to many Illinois farmers this year, since there will now be plenty of hog feed to supplement the short crop of corn from the 1934 crop, according to W. E. Carroll, chief in swine husbandry at the College of Agriculture, University of Illinois.

Cats is worth 90 to 95 per cent as much as corn for hog feeding, if the pig takes up only about one-third of the ration. This has been shown in extensive feeding tests on the college farm. Consequently the present price ratio between corn and cats makes it profitable for most Illinois farmers to reduce at least a third of the corn in their grains ration with cats. Where cats are not available, pig feed, if used exclusively, the cats are worth only 70 to 75 per cent as much as corn, Carroll stated. Gains are slower as the percentage of cats in the ration increases and more feed is needed for a given amount of gain.

-1-

Record Soybean Crop Will Build Up Reserves Of Hay

A record acreage of soybeans offers Illinois farmers an excellent way of rebuilding hay reserves this year, and the problem of rainy weather hay-stings will be minimized if the beans are cut at the right time, according to J. C. Hackleson, crop extension specialist at the College of Agriculture, University of Illinois.

The beans may be cut for hay any time from the forming of the beans in the pods until they are about three-fourths ravel red. The best time, weather being favorable, is when the seeds have developed just enough to touch each other in the pods. At this time there are few if any dry leaves at the base of the plants, and the farmer will get the maximum yield of good quality hay.

Since soybean hay is slow to cure after the fall weather begins, it should be cut as early as possible after the seed begins to form, Hackleson said. For most of Illinois the last week in August is generally the most ideal time for putting up soybean hay. The weather is usually dry and fairly hot, and the heavy dew and cooler days of fall have not yet come.

Bean hay may be cut either with a mower or a grain binder, although the mower is usually the most satisfactory for Illinois conditions. If cut with a mower, the hay is generally allowed to cure to some extent in the swaths and then raked into windrows before the leaves are dry enough to chatter. Some farmers, however, prefer to rake the hay immediately after mowing and allow it to cure in the windrow. This has been found an excellent method if the weather is dry and hot.

A grain binder can be used in dry weather, but the bales must be small and loosely tied. If fall rains occur as they did in 1934, each bundle will probably develop a moldy core about two or three inches in diameter.

-M-

Rainy Weather Making Lespedeza a Popular Hay Crop

Lespedeza, the legume which has spread faster than any new crop introduced into Illinois in recent years, is gaining added popularity in a season like this when farmers are beset with the problem of curing hay because rains, according to W. B. Nevens, dairy cattle feeding specialist at the College of Agriculture, University of Illinois.

Being light stemmed, slower to mature and comparatively quick to cure, lespedeza fits into a summer like the present when frequent rains hamper the putting up of alfalfa and similar crops which require a longer time to cure properly and must be cut early in the season.

Tests at the college have shown that Korean lespedeza and alfalfa are practically equal in feeding value. The only noticeable difference is that the cattle show a slight preference for alfalfa when both hays are available.

Lespedeza, cut at the full-bloom stage, has been found to have 60 per cent leaves and to show 17 per cent protein and 3 per cent lime. Good quality alfalfa hay is slightly less leafy, registering 49 per cent. However, alfalfa has 16 per cent protein and 4.5 per cent lime.

Milk production is practically the same whether cows are fed alfalfa or lespedeza. In college tests average daily production was less an oxactly 40 pounds of 4 per cent milk for each cow regardless of which hay has been fed. Nevens stated. Nor have the two hays shown any variance in their ability to produce gain in added to young dairy cattle.

To make the best quality hay, lespedeza must be cut at about the full bloom stage, which is late August or early September in Illinois. As the seed stage approaches, the hay loses its palatability. Korean lespedeza reaches the full blooming stage in southern and central Illinois in late August or early September.

## Cross-Cultivating In Spring By Corn Checks Erosion

Destructive erosion on more than  $\frac{1}{2}$  million acres of Illinois farm land can be materially reduced during the remainder of the year if farmers will only cultivate across the slope when they "lay by" their corn for the season according to H. L. Buckardt, chief soil erosion extension specialist of the College of Agriculture, University of Illinois.

More than 75 per cent of the estimated 7,589,600 acres of corn in Illinois this year is on land where erosion will wash away top soil, drain off valuable fertility and jeopardize future crop unless proper protective measures are taken, he said. If the corn is cultivated across the slope at the last cultivation, each shovel mark will serve as a miniature terrace to help check the flow of run-off water, he pointed out.

Experimental results at Betaary, Mo., show that as much as 74 tons of soil an acre can be lost annually from land sloping 2 per cent that is growing continuous corn and that is cultivated up and down the slope, Buckardt reported.

"The common practice in Illinois is to check the corn rows the long way of the field, which in many cases results in corn rows running up and down slopes. Consequently after the corn is cultivated, each row serves as a surface drainage unit for the slope.

"The one-time favored opinion that crops should be planted up and down the slope so that each row could take care of its own water is no longer a desirable one. The best practice is to plant and cultivate corn so that the rows run across the slope. Each row ridge then acts as a check on the flow of run-off water and thereby reduces the losses from erosion.

"While cultivating across the slope is always sound erosion prevention, it is most important when the corn is laid by at the last cultivation. The field will, in most cases, remain without further cultivation throughout the summer, fall and following spring. If the common practice is followed, the plow ridges and furrows up and down the slopes during this long period of time will create ideal conditions for serious losses from erosion."

Cultivating across the slope is only one of the practices which must be more generally adopted if soil erosion is to be controlled, it is pointed out by specialists of the college. Seriousness of the problem is revealed in the soil survey reports of the college which show that there are more than three million acres of Illinois land that are so subject to destructive erosion they should never be farmed. There are another three million acres that are subject to serious erosion and are suitable only for orcharding, permanent pasture or timber. There are more than 12,000,000 acres where erosion control practices are necessary to maintain the productivity of the land.

## U. of I. Station, W I L L, Reporting Grain Markets

A five-minute report of the Chicago grain market is now being broadcast daily except Sunday at 5, 9.55 and 10:55 a.m. by the University of Illinois radio station, W I L L. It broadcasts on 890 kilocycles.

-M-

Wet Weather During Haying Heightens Danger of Fire

An estimated annual loss of one million dollars in Illinois from fires caused by the spontaneous combustion of wet hay may be increased this year unless farmers take extra measures to prevent the heating of hay which has been dampened by the frequent rains, according to E. W. Lemann. He is head of the department of agricultural engineering at the College of Agriculture, University of Illinois.

Hay which goes into the barn or stack while it is damp from rains or dew is almost sure to heat. In many cases the temperature only gets high enough to spoil the hay, but there are frequent cases where enough heat is generated to start a fire. The heat is caused by bacterial and chemical actions which are speeded up by the presence of excess moisture.

The best preventive is to avoid putting damp hay into a barn or stack. However, frequent rains this summer have made that impossible in many cases, Lemann said. If the moisture is only slight, the sprinkling of salt on the hay as it goes into the barn or stack will usually slow down the heating enough to prevent combustion. Not more than 20 pounds of salt should be used to each ton of hay.

Spreading the damp hay out in a thin layer will allow it to dry more rapidly. However, such hay should not be piled on top of dry hay, as the dry hay will burn much more readily and may catch from the heat of the damp layer on top.

When long hay begins to heat, it is dangerous to move any of it until the whole pile has been thoroughly soaked. A slight disturbance may admit enough oxygen to cause the hay to burst into flame. Chopped hay can be handled readily provided enough water is handy to sprinkle any burning portions which may be removed from the pile.

A leaky roof is a possible source of danger as well as the means of spoiling considerable hay.

-M-

Alfalfa Is Good Summer Pasture When Bluegrass Fails

With the bluegrass pasture season rapidly coming to a close in most sections of Illinois, the record acreage of alfalfa growing in the state this year offers a satisfactory substitute, said J. C. Hackleman, crops extension specialist at the College of Agriculture, University of Illinois. Alfalfa is especially good in maintaining the flow of milk from dairy cows.

Danger of bloat is very slight if stockmen will follow a few simple precautions, Hackleman said. In fact, there is little more danger than in pasturing red clover.

Two general precautions should be observed in pasturing alfalfa. First, it should not be pastured when it is wet or when the cattle are hungry. Second, the cattle should be fed plenty of dry forage and have access to plenty of water at all times.

Alfalfa that is wet, either from rain or a heavy dew, is much more likely to bloat the cattle than is alfalfa that is dry. The danger of bloat is increased when the cattle are turned on to the pasture while hungry, for they will gorge themselves with the green, succulent feed. A regular feeding of grain and good forage just before the cattle are turned on to the pasture will cause them to eat more leisurely and in smaller amounts. Thus the alfalfa becomes a part of the summer ration rather than the entire ration.

Such dry forage as alfalfa hay and oats straw along with plenty of water at all times will aid materially in avoiding alfalfa bloat.

Pasturing of alfalfa will not injure the crop if the pasture is not overloaded, Hackleman stated.

-M-

### Proper Timing Of Peach Picking Increases Prospects

With prospects for the best crop in years, Illinois peach growers can still further increase their advantage this year by delaying harvest a week or so longer than is the usual practice, according to M. J. Dorsey, chief in pomology, and R. L. McMunn, associate, at the College of Agriculture, University of Illinois. Prospects now are for a fine quality crop of 5,430,000 bushels, which is double the five-year average for 1928-1932.

Tests made at the college show that the same number of peaches which will make only 100 bushels if picked on August 15 will make 124 bushels if not harvested until a week later. Harvesting at the right time thus allows the peaches to reach their maximum size.

Many peach growers in the past have harvested the major part of their crop during the early part of the ripening season just after the color of the fruit began to change from green to yellow. This was done in the belief that early marketings would net greater cash returns, were better in transit and escape brown rot.

Early-picked fruit does not reach its maximum size. Consequently the yield is below that of peach crops harvested later in the ripening period. The advantage gained from early marketings as well as from the better keeping qualities of the fruit picked at the half ripe stage are outweighed by the smaller size of the peaches, it has been indicated by the college tests.

Elberta and other yellow varieties of peaches are at the ideal harvesting stage when the skins have changed from green to a light yellowish green and have about a 25 per cent blush appearance. At this stage the fruit will be of almost maximum size, but still be firm enough to withstand shipping.

Peaches should never be left on the trees until they become "soft ripe." While they may be excellent to eat fresh at this stage, they will not withstand shipping or storage.

-M-

### Using Resistant Wheat Only Known Way To Check Rust

Planting resistant varieties is the only known means by which Illinois wheat growers can control outbreaks of yellow leaf rust, such as have occurred quite generally over the state this year, said Benjamin Kocler, crop disease specialist at the College of Agriculture, University of Illinois. Being a fungus disease, yellow leaf rust is spread by spores. Moist weather increases the chance of infection. Unlike some kinds of rust it requires no alternate host, since the spores infect the new crop of winter wheat in the fall and live there until spring. So far, the development of wheat that is resistant to leaf rust is still in its infancy, according to J. T. Bonnett, plant breeding specialist at the college. However, a few varieties that are partially resistant to the disease have been developed and are available.

-M-

### Rabies Control hinges On Following Simple Measures

Instead of increasing as it now is, rabies among dogs and other animals could be practically eliminated if every person would follow a few simple precautions, according to Dr. Robert Graham, chief in animal pathology and hygiene at the College of Agriculture, University of Illinois. Last year Illinois had 17 dog cases and eight human fatalities as compared with only 191 dog cases and four human fatalities in 1935. Avoiding the handling of strange dogs, eliminating ownerless or stray dogs, placing rabid dog suspects under observation, consulting a physician in the case of dog bites, vaccinating all dogs annually and obtaining microscopical diagnosis of rabid dog suspects are the chief precautions in suppressing rabies, Dr. Graham said.

## Peach Prospects Good, But Quality as Best in Years

Although the Illinois peach crop will be a smaller than earlier prospects indicated, consumers have something to look forward to in the way of higher quality in the fruit which will be marketed this year, according to V. W. Kelley, horticultural extension specialist at the College of Agriculture, University of Illinois. The Illinois peach crop is expected to be harvested between August 5 and 25.

Recent experiments were in which it was clearly demonstrated how both quality and yield of peaches are improved by delayed picking. This has paved the way for the higher quality which consumers of Illinois peaches will get this year, Kelley said. Convinced by the results of these tests, many growers are expected to let the fruit ripen on the tree somewhat longer than has been the practice in the past with the result that the natural flavors will develop, Kelley explained.

"Peaches picked too green before the ground color begins to turn yellow never acquire the natural flavor and aroma which are essential to that high degree of palatability that is expected in this fruit. Because peaches are generally picked somewhat green for distant shipment from one state to the other, Illinois consumers are more likely to get highly-flavored fruit when they buy Illinois-grown peaches.

"Not only does delayed picking increase the quality of the peach, but also it greatly increases production because of the larger size of the fruit. In the 1934 experiments fruits harvested seven days after the normal picking date made about 25 per cent more fruit than they would if picked at the usual time. That is, each 100 bushels of fruit made on the normal picking date had increased to 125 bushels seven days later. The fruit not only was larger but also held up well in transit and storage and was of much better quality than the fruit picked earlier."

Latest estimates place the Illinois crop at not more than half the bumper crop of 4,000,000 bushels of 1934. Damage by hail and a late drop after thinning are largely responsible for the smaller estimate. Because of the reduced yield the Illinois crop is expected to move at a price which should bring a fair return to the grower, Kelley said.

-M-

## Snows And Fairs Keeping 10,000 4-H Club Members Busy

Illinois' 25,000 4-H club members are in the midst of their busiest season with an estimated 150 snows and fairs of various kinds scheduled between August 1 and December 15, according to reports reaching the extension service, College of Agriculture, University of Illinois. The majority of these events will take place during the coming six weeks.

Thirty-eight club snows will be held in 45 counties during August, it is shown by partial reports from those counties. The same reports indicate that July, with 19 snows already held, will probably be the second busiest month. September comes third with 17 club snows scheduled, while October has two and November and December each have three. Club workers at the college estimate that approximately half of the club snows and fairs were included in the partial report from 45 counties.

-H-

### Pastures Will Be Made Or Ruined In Next Few Months

Pastures have recovered remarkably from the drought damage of 1934, and farmers can hold their gains by careful management during the rest of the summer, according to crops specialists at the College of Agriculture, University of Illinois. Protecting pastures at this critical period of the year also will help promote the shift from grain to more grass and legumes, it was pointed out.

Overgrazing, poor soil, dry weather or any other condition which tends to slow the growth of pastures will give weeds and grass a chance to get started. Last summer's drought, which killed out large patches of pasture grass, gave the weeds an excellent chance to get started.

Getting rid of these weeds is one of the first measures to be followed in the pasture management schedule for the rest of the summer, the specialists say. While the small patches may be grubbed out or killed with chemicals, mowing is the best eradication method for larger areas. Mowing prevents many annual plants from producing seed and at the same time discourages growth of the perennials.

Mowing, grubbing and poisoning will not get all the weeds the first year. These practices must be continued from year to year, and the farmer will need to be on the alert for new patches of weeds.

Use of adapted seedling mixtures and proper fertilization will help combat the weed menace and at the same time will build up the pastures. One mixture which has given good results on the college farm is composed of 5 pounds of Kentucky bluegrass, 3 of red top, 10 of bromegrass and 2 of white clover. A good mixture for northern and central Illinois pastures where the soil is moist and contains medium to high amounts of available phosphorus is composed of 4 pounds of sweet clover, 4 of red clover, 1 of white clover, 6 of bromegrass and 4 of timothy. A recommended combination for northern and central Illinois pastures with sweet soils but which are low in available phosphorus includes 4 pounds of sweet clover, 3 of alsike clover, 4 of lespedeza, 4 of timothy and 6 of red top.

A mixture that can be used on southern Illinois pastures with slight to medium acid soils that are medium to high in available phosphorus contains 2 pounds of alsike clover, 3 of lespedeza, 3 of bluegrass, 3 of orchard grass and 6 of red top.

Many times weeds get into the pasture through impure seed. This can be avoided to a large extent by the purchase of guaranteed seed from reliable dealers.

-11-

### Culling Will Fix Flock For Better Poultry Outlook

A favorable fall and winter outlook for egg prices promises added benefits from the careful and thorough culling of the laying flock this summer and fall to get rid of the non-layers and other "boarders," according to H. H. Alp, poultry extension specialist of the College of Agriculture, University of Illinois.

Good layers not only will produce more eggs for the favorable markets that are now in prospect but also will pay better returns on the feed they eat, he said. Since the average hen uses six to seven pounds of feed a month, non-layers can soon "eat their heads off," he added.

How close to cull the flock depends upon its size, average production, number of pullets available for replacement and other factors. In a high-producing flock the culling can be done very closely, since the percentage of non-layers will be small. On the other hand the producer who has only a limited number of pullets coming along may wish to cull rather lightly in order to avoid depleting his flock.

-12-

Prospects Of Soft Corn: Trench Silo In Limelight

With condition of the state's 7 $\frac{1}{2}$  million acres of corn, mostly late planted, containing below average, trench silos bid fair to become an important factor in the preservation and use of soft corn which may be prevalent in many sections of Illinois this fall, it is said by E. W. Lehmann, head of the department of agricultural engineering at the College of Agriculture, University of Illinois.

Soft corn is difficult to store in cribs, bins or barns, but makes excellent silage. Since it is cheap, simple to construct and costs less to fill, the trench silo is said to be one of the best means by which Illinois farmers can store this soft, immature corn. The only construction equipment needed is a plow, slip and tractor or team of horses. Two men with this equipment can construct a trench silo in from two to four days depending upon the size.

The silo should be constructed with a slight slope in the sides and on high ground where there is less likelihood of standing water. If a bank or slope is available, the lower end of the "trench" may be left open as a natural drain.

Silage that will freeze and kept higher in the middle than on the sides during the filling process, said Lehmann. This causes the silage to settle in a rounded manner after the finishing of the stack. Covering the silage with about a 2 or 4 inch layer of fine cut straw followed by a layer of dirt will help keep out air and prevent spoilage.

-4-

Hog Prices Put Price On Curbing Loss From Disease

Smaller numbers of hogs combined with higher prices now make it more worthwhile than ever for farmers to vaccinate their pigs and take other precautions against losses from cholera and other diseases, it is pointed out by Dr. Robert Graham, chief in animal pathology and hygiene at the College of Agriculture, University of Illinois.

Vaccinations should be performed by a competent veterinarian and certain precautions taken, Dr. Graham said. Chief among these precautions is to keep the hogs on light feed during the vaccination period.

Hogs that are used early before, during and just after vaccination occasionally fail to become immune to cholera, experimental tests have shown. While they may be safe from the disease for a short time, they will become susceptible as soon as the effect of the serum wears off and may even develop the disease from the vaccine.

The best method of handling hogs that are to be vaccinated against cholera is to put them on a very limited feed for at least three days prior to vaccination, Graham said. They should be kept isolated from untreated hogs and gradually brought back to full feed after being vaccinated.

Another question which always arises when hog cholera is in the vicinity is that regarding the means of spreading the disease. Experiments at the U. of I. College of Agriculture and in other states have shown that the stable fly which bites animals and humans so viciously about this time of the year is one of the more important factors in the spread of cholera.

The stable fly appears to be a worse offender than the house fly, although house flies have been known to transmit the disease.

Indications are that man is of less importance than was formerly thought in spreading cholera. In fact man has been shown to have very little effect as a spreader.

## Soil Erosion in Illinois

Soil erosion is a serious problem in Illinois. It is estimated that 15 to 20 per cent of the soil in the state has been eroded. The Agricultural College of the University of Illinois is conducting a soil survey of the state to determine the extent of the problem and to develop methods for its control.

Soil erosion is a process by which the soil is removed from its original position and is transported to another location. It is caused by water and wind. The most serious erosion is caused by water. It is most common on steep slopes and in areas where the soil is thin and the vegetation is sparse.

Aug. 23 and 24, 1935 To Be Featured At State Fair

A chorus of 11 voices, selected from nine different countries that will be competing for a prize of \$1,000 in voice music will be featured on the August 23 program of the Illinois State Fair at Springfield. It is announced by D. E. Lindstrom, rural school extension specialist at the College of Agriculture, University of Illinois.

The contest is under the supervision of Lindstrom and is one phase of the musical relations now being carried on between the various parts of the state by the extension service. The large chorus recital will be held in front of the grandstand at 1:30 P.M. and will be conducted by Lincoln F. Demming, instructor in music at the U. of I. At the present time Demming is visiting the various competing counties to assist the choruses in preparing for the state contest.

Counties entering are Boone, McHenry, Kendall, McLean, Champaign, Iroquois, Shelby, Sangamon and Lincoln. First prize will be \$1,000, second \$110, third \$100, fourth \$50, fifth \$25, sixth \$10 and the last three \$50 each. Additional prizes will go to the three grand choruses, each \$500 each.

So long this year will be the best of the number in each chorus, distance travel into reach the state fair and degree of balance among the various parts of the chorus, Lindstrom said.

The program of recitals to be given during the festival. In addition, the musical features of the festival will be presented. The four choruses of the various counties are: "The Page of Country," by Bickberg, "The Merry Dancers," by Bickberg, "My Bonnie Lads," by Bottomley and "Break Forth O' Brains As Heaven's Light," by Bach.

The following are the names of the persons in the various counties are as follows: Boone, Harold Dickson, farm adviser; McHenry, E. C. Foley, farm adviser; Champaign, Mrs. R. T. Williams, farm adviser; Iroquois, Mrs. Virginia Conn White, home adviser; Lawrence, W. T. Taylor, farm adviser; Kendall, Mrs. Grace Burman, Watske, director, and Dr. Ruth F. Brown, farm adviser; McLean, W. P. Miller, farm adviser; McHenry, Mrs. Clara George Sweet, home adviser; McLean, Mrs. T. W. Kwasigroh, Randolph, chairman, and Miss Clara Brian, home adviser; Sangamon, Mrs. Homer Kearns, Springfield, director, and Elvir Bay, farm adviser; Shelby, Mrs. Winifred Bolden, Moweaqua, chairman, and W. S. Bates, farm adviser.

-1-

Consumers Have Rare Opportunity In 1935 Peach Crop

With Illinois about to harvest its best peach crop in five years, consumers have a rare chance to fill their baskets with big and low in a supply of quality peaches against the years when the crop will again be short or a failure, it is pointed out by V. W. Kelley, horticulture extension specialist of the College of Agriculture, University of Illinois.

Not a few households with an eye to their food costs and their storage cellar supplies are planning to can and preserve enough peaches for at least a two year's supply, he reported.

The Illinois crop of Elbertas, the principal variety in the state, is expected to be harvested between August 15 and 25.

But since 1931 have consumers had a chance at an Illinois peach crop that is as large and as the one this year, and there is no certainty as to when there will be another such crop. The peach is a hard fruit which seldom survives temperatures below 20 degrees Fahrenheit. Consequently production is somewhat irregular in the latitude of the middle west. The Illinois crop this year is estimated at about half that of the crop of 4,000,000 bushels in 1931.

-M-

Present-Day Hogs Not Best Suited For Market Needs

None of the present-day types of swine effectively meet current market requirements being set by the low foreign demand for pork and lard and the domestic preference for small, lean, firm cuts, finished bellies and a minimum of lard, according to experiments conducted at the College of Agriculture, University of Illinois. The tests have just been summarized in a new bulletin, "Value of Present-Day Swine Types in Meeting Changed Consumer Demand."

Of the swine types now common on farms of the country the intermediate comes nearest to meeting present-day demands, it was found in the tests by Sleeter Bull, associate chief in meats; F. C. Olson and J. E. Hunt, formerly assistants in animal husbandry; and T. E. Carroll, chief in swine husbandry at the college.

An ideal hog would combine the quality and plumpness of the intermediate type, the length of the range and the early maturity of the chaffy.

Intermediates rated good as to gains and dressing percentages, side and cutting percentages of wholesale cuts, quality of loins and leins and amount of lard stock produced. Their market grade was good in most cases but a few lacked finish, according to the bulletin.

Poor finish and firmness of the meat, especially the bellies, were the main defects in placing the chaffy type second. There was also some tendency toward too much lard production from this type.

The range type, which was rated third, showed favorably gains and dressing percentages, good cut sides, good quality loins, fair leins and the right proportion of lard stock. However, the bellies were unfinished and soft, and the carcasses generally were lacking in firmness.

-11-

\$20 Cave Pays Big Returns In Protecting Egg Quality

Twenty dollars' worth of material and a few days labor put into the construction of an egg storage cave have helped Lyman Bunting of near Altion prevent low quality eggs which cost Illinois poultrymen thousands of dollars every year. Bunting, who has been cooperating with the extension service of the College of Agriculture, University of Illinois, on improved poultry practices for several years, has added approximately 5 per cent to his egg sale returns by building this cave, it is estimated by H. H. Alp, poultry extension specialist at the college.

Having built up production of his flock of 500 White Leghorns to a high point by following approved practices, Bunting recently became interested in getting a better cash return from the sale of his eggs. His first step was to start grading the eggs at home and shipping them direct to distributors who were paying prices based on grades. This practice brought considerably higher returns than the old method of selling the eggs on the count basis.

With the coming of warm weather, low grade eggs were found in each shipment despite the fact that Bunting gathered the eggs several times daily, graded them according to size and color and shipped them promptly. His difficulty was a lack of cool storage space.

He built a small cave about six feet wide, 10 feet long and seven feet deep. Cull bricks secured from a local brick yard at a small cost were used in constructing the cave, which is covered with dirt and vines to help keep out the heat of the sun. Trays built of hardware cloth are set up in the cave so that freshly gathered eggs are laid out in single layers to cool rapidly.

Because of this rapid cooling and storage of the eggs until they are ready to be shipped, Bunting is finding that fewer of his eggs are cull and because of spoilage.

## Lespedeza Is Ridding Her Place As A Leading Legume

Lespedeza, a relatively new crop already grown in Illinois to the extent of 17,000 acres, promises to become one of the leading legume crops of the state, especially on soils of lower productive levels, according to experiments conducted by the College of Agriculture, University of Illinois during the past 43 years and recorded in a new bulletin, "Lespedeza in Illinois."

The crop's true value is a course to be determined. It is drought resistant, fair, free from disease and insect pests, and has a self-seeding quality. It is stated in the bulletin prepared by L. J. Sieber, crop production specialist; O. H. Beard, soil biologist; and F. W. Fisher, chief in soil experiment fields of the college.

Lespedeza is valuable not as a substitute for alfalfa or other crop for other legume, but for its ability to thrive where alfalfa and sweet clover will not grow satisfactorily. While it grows best on well drained, non-acid soils, lespedeza will do fairly well on soils red of any soil and poor in quality.

Thus it provides farmers with a legume which will set in motion the processes of soil improvement and erosion prevention without a large initial outlay for fertilizing materials.

Although the legume will grow in practically all parts of the state, it is better adapted to the southern and central portions, since it is resistant to dry, hot weather and sensitive to freezing weather in early spring and late fall, the bulletin stated.

Thorough liming is necessary where lespedeza is grown on soil for the first time. If the soil is acid, liming is desirable.

The legume is valuable mainly as a pasture or soil improvement crop, although it produces a very satisfactory hay, and is useful in retarding soil erosion. As a pasture crop it furnishes the best pasture beginning about July 1 and continuing until late fall. It is also valuable as a seed crop, although the increasing acreage indicates seed will become less important as a cash crop in the future.

Annual varieties best adapted to Illinois conditions are headed by Korean, although under certain conditions Tennessee 76, Kobe and Common may be preferable. In the northern part of the state Harbin is the only variety that may be expected to be self-seeding. Sericea, a perennial, is showing promise as a hay crop for southern Illinois, according to the bulletin.

-11-

## Davis To Become Farm Adviser In Pulaski-Alexander

L. L. Davis, formerly vocational agriculture teacher at Chester, will start work September 1 as farm adviser in Pulaski and Alexander counties with headquarters at Mounds, it is announced by Fred J. Schiffer, state leader of farm advisers at the College of Agriculture, University of Illinois. He succeeds F. H. Gorham who resigned April 11 to accept a position with the AAA land policy section.

-12-

Smaller Peaches Are Not Bargain When Waste Counted

Unless small peaches are offered at extremely low prices, consumers will be money ahead if they buy the larger, high-quality fruit being harvested from Illinois orchards at the present time, stated M. J. Dorsey, nemology chief at the College of Agriculture, University of Illinois. Too much of the "bargain" prices that are paid for small peaches goes into seeds and peeling, he pointed out.

A bushel of large peaches two and one-half to two and three-fourths inches in diameter contains only three pounds of seeds, according to tests made at the college experiment station. In contrast a bushel of small peaches one and one-half to one and three-fourths inches in diameter contains about six and a half pounds of seeds with a consequent decrease in the amount of useable fruit flesh.

Not only do small peaches have a greater proportion of seed to flesh but also they are more tedious to clean, peel and prepare for canning, Dorsey explained. Those three inches in diameter run about 100 to the bushel, while those measuring two inches run close to 300 and the smaller ones approximately 1,000. Since each peach must be handled separately in the canning process, the size becomes an important factor in the use of time.

Another fact brought out by tests on the various sizes of peaches is that the smaller fruits have far more skin to the bushel than do the larger sizes. The smaller sizes have about 35 square feet of skin while the larger sizes run as low as 23 square feet. Since peeling involves both time and some waste of fruit, the smaller amount of skin is a point in favor of the large peaches.

Small peaches are seldom economical in the long run, except where the fruit is to be used for spicing. In that case the smaller sizes may be advantageous if the price is low.

-2-

Quality Of Onions Went By Proper Harvesting Methods

Onions both in home gardens and on commercial truck farms are of unusually good quality and size in Illinois this year, according to reports reaching B. L. Weaver of the vegetable gardening division at the College of Agriculture, University of Illinois. By following the best harvesting and curing methods, producers can preserve the quality of the product either for market or for home storage, Weaver said.

When an onion ripens properly, the neck shrivels first and the tops fall over while they are still green. After the tops have fallen, they gradually turn yellow and finally become dry and brown if the onion is not pulled. The best time to harvest is just after the tops have started to turn yellow, Weaver stated. If left much after that time, the onions are likely to start a second growth, especially if a few good rains fall after the onions have ripened. Those that have once started a second growth are useless for storage and must be used as soon as harvested.

When the leaves of the onion start drying from the top down while the neck remains rigid, the vegetable is not ripening properly and should not be saved for storage or shipment.

Onions may be dried, or "cured," either by placing them in windrows or in shallow crates. Where they are placed in windrows, the tops should be left on to protect them from sunburn. This method is satisfactory where good weather prevails. It is safer, however, to twist the tops from the onions as they are pulled and place them in shallow crates, Weaver said. The crates should have slatted bottoms and sides so that air may circulate freely among them. The common sized crate is four feet long, three feet wide and four inches deep.

-11-

Interest In Horse Pulling Contests Showing Increase

Growing interest among farmers in more and better horses and the consequent strengthening of horse prices is reflected in the rising popularity of horse pulling contests being staged in Illinois this summer and fall. According to F. T. Robbins, animal husbandry extension specialist at the College of Agriculture, University of Illinois.

Contests have already been held at Wheaton on June 15, Charleston on August 5 and Mt. Sterling on August 8. Other contests on the list are Pinckneyville, August 13; Albion, August 15; Watska, August 17; Springfield, August 19 and 21; Acsville, August 23; Pontonica, August 24; St. Joseph, August 27, LaFayette, August 28; Augusta, September 3; Sandwich, September 4; Knoxville, September 5; Bridgeport, September 6; Monticello, September 7, and Farm City, September 10.

These contests, supervised by Robbins, have been useful in illustrating the pulling value of horses, as well as the importance of proper breeding and training to increase the pulling efficiency of horses.

Adding interest to the contests this year is the fact that a new State record has already been established for teams weighing more than 3,000 pounds. This record was established at Wheaton on June 15 when a pair of grade Percheron geldings owned by Charles H. Matt, of Sandwich, lifted 4,400 pounds 17 feet on the U. of I. dynamometer. The team weighed 3,550 pounds. This team, weighing 4,200 pounds, defeated several of the best teams from neighboring states, as well as Illinois entries.

In the class for teams weighing less than 3,000 pounds the record established by the team of Willard Roads, Springfield, in 1931 is still unbroken. These two horses, weighing 2,900, lifted 3,705 pounds to a height of 17½ feet.

Scheduling of a stallion pulling contest at Lincoln Field, Creston, on October 12 marks the first time in the history of draft horse breeding that ability to move a heavy load in a public contest will be used as a standard of merit for draft stallions according to J. L. Edwards, chief of horse husbandry at the College of Agriculture, University of Illinois.

This contest, the first of its kind in the world, is being held by the Horse and Mule Association of America in cooperation with the college. The pulling power of the stallions entered will be measured by the U. of I. dynamometer under the supervision of F. T. Robbins, animal husbandry extension specialist. Ten cash prizes totaling \$1,500 will be awarded to the owners of the 10 best pullers.

-4-

May Apple Rust Not Likely To Damage Many Years Crop

Apple producers of Illinois, beset by the quince rust disease which is causing some losses especially in the western part of the state this year, can console themselves by the fact there will be practically no damage from this disease in 1934, according to H. W. Anderson, fruit pathology specialist at the College of Agriculture, University of Illinois.

Quince rust, a fungus disease rarely observed on apples before this season, spends a part of its life on the red cedar trees that grow in many parts of the state. The spores which would normally attack the 1934 apple crop were destroyed to a large extent by the hot, dry weather of 1934. Consequently, little infection is expected next year.

The rust attacks the apple, eating the fruit tissues rather than the leaves as the black rust spot. As the apple grows, a greater liability to infection is developed in the diseased areas, disfiguring the apple and reducing its value either for marketing or home use. Quince rust does not ordinarily attack the leaves or do any harm to the cowhorm rust.

## More Youngsters Becoming Active In Local Affairs

An increasing number of Illinois rural young people are becoming factors in the betterment of their home communities through their activities as groups, it is reported by the extension service of the College of Agriculture, University of Illinois. These groups not only help improve farming and homemaking but also contribute to a richer and happier social life. Active in two counties in 1931, such groups may now be found in 49 counties.

Counties in which young people older than 4-H club age but still too young to take their places among the grown-ups have become active since 1931 are: Adams, Bond, Boone, Bureau, Campaign, DeWitt, DuPage, Edgar, Edwards, Effingham, Hancock, Henderson, Iroquois, J. Daviess, Kane, Kendall, Knox, Lake, LaSalle, Lawrence, Livingston, Macon, Macoupin, Madison, Morgan, Marshall, Mason, Massac, McDonough, McHenry, McLean, Mercer, Monroe, Pike, Pitts, Pope, Pulaski, Putnam, Randolph, Richland, Scott, Shelby, Tazewell, Warren, Washington, White, Whiteside, Will and Woodford.

Activities of these young people's groups are varied. Twenty-five Kane county youths entered community affairs by staging a series of meetings two weeks apart and bringing other young people to each of the meetings to interest them in the county's problems and possibilities. Richland county youngsters operated all concessions during a recent farm picnic and turned the profits over to local agencies working for the betterment of agriculture and home economics.

Other groups have attacked economic problems of the home and community. In Adams county the young people are making studies to determine whether or not older children remaining on the farm can produce additional income to compensate for their living expenses.

Fifty-three Macon county young people are attempting to enlarge on the recreational and good fellowship facilities of the county as well as to find ways of broadening their general knowledge. Livingston, Hancock and Bond county groups are interested in "Know Illinois," one of the projects prepared recently by the extension service to meet the needs of young people's groups.

Older boys and girls of Scott county have found the "Building an Outdoor Home" project attractive. They have also shown interest in drama production, as has the DeWitt county group. These projects along with "Know Illinois" were arranged by G. S. Randall and Miss Cleo Fitzsimmons, junior club extension specialists at the college, in response to demands from the groups. Assistance in preparing the "Build an Outdoor Home" project was given by Max Huller, landscape gardening extension specialist, while D. E. Lindstrom, rural sociology extension specialist, has helped with the project on drama.

In Woodford county a group of young women are making detailed studies of everyday art as applied to their individual needs in clothing designs and others. In addition this group is finding foreign cookery not only interesting but also helpful in bringing new foods to the party table.

Many other activities are reported from among the 49 counties, but in all cases the young people's groups are attempting to follow a balanced program for the promotion of better home and farm practices and a happier community life.

### Fertilizer Trials Solve Problem In Sweet Corn Crop

Although growers of sweet corn, one of Illinois' most important crops, have all but abandoned use of commercial fertilizers because of poor results, it has now been demonstrated in six years of experimental work by the College of Agriculture, University of Illinois that proper use of such fertilizers markedly improved both the yield and time of maturity of sweet corn.

The test results are reported in a new bulletin, "Fertilizer Requirements of Sweet Corn," by W. A. Helsen, division of agriculture, and M. C. Gillis, former member of the division, who conducted the experiments.

Illinois is the leading state in acreage and production of sweet corn, but growers have taken losses for some time because yields, quality and maturity of the grain were not what they should be. Although commercial fertilizers have been resorted to, their use has been abandoned in all except isolated instances because of very slight or even negative results. Up until the time of the Illinois experiments but little reliable information was available as to the cause of this disappointing showing and the best methods of using fertilizers.

Of 65 different fertilizer combinations which were tried out during the six years of the tests, the one which gave the best and most consistent results was an 0-16-12 formula (no nitrogen, 16 parts phosphorus and 12 parts potassium) applied at the rate of 400 pounds an acre and supplemented with 50 pounds of side-dressed sodium nitrate. This treatment used in a rotation system including legumes increased the yield of marketable ears 41.56 per cent.

Under some conditions the 0-16-12 analysis may be reduced with advantage to 0-16-6, but the amount of nitrate used as a side-dressing should not be changed, it was brought out in the tests.

Other recommendations growing out of the tests were: (1) Use a rotation including legumes in order to get maximum responses from commercial fertilizers. (2) Where nitrogen is omitted, an additional 50 pounds of an 0-16-6 fertilizer an acre. (3) If it is desired to apply less than 400 pounds of fertilizer (without nitrogen) an acre, an 0-16-6 combination will probably prove superior to 0-16-3. (4) Mineral fertilizers applied without nitrogen should contain not more than 6 per cent potash. (5) An application of 400 pounds of an 0-16-14 fertilizer plus side-dressed sodium nitrate at the rate of 50 pounds an acre may prove profitable under some conditions. (6) Nitrate of soda should be applied 30 to 60 days after the corn is planted.

### Illinois A Leading State In Meeting Of Nut Producers

Illinois will be well represented at the twenty-sixth annual convention of the Northern Nut Growers' Association at Rockport, Ind., September 9 and 10 with six people on the program, it is announced by Dr. A. S. Colby, chief in small fruit culture at the College of Agriculture, University of Illinois.

Heading the convention will be President Frank H. Frey, of Chicago, who will open the program September 9. Development of the nut industry in Illinois will be discussed by L. E. Sawyer, forestry extension specialist at the college, during the evening session of the first day. During the morning session of the second day Dr. Colby will outline the next steps to be taken by nut growers of Illinois. He will be followed by R. B. Endicott, of Villa Ridge, who will discuss chestnut growing in southern Illinois.

A. M. Whitford, of Bolina, will tell the delegation something about shell-nut tree propagation during the afternoon session of the second day, and J. S. Dool, of Shattuck, will discuss the new Kaskaskia River pecans and blights.

-15-

### Plenty Of Feed Brightens Dairy Prospects In State

With plenty of good roughages and grains being produced in Illinois this year, dairymen can forego the skimpy rations of drought times and again feed their cows more profitable and better balanced combinations, says C. S. Rhode, dairy husbandry specialist at the College of Agriculture, University of Illinois.

Those who cull out their lowest producing cows and use the plentiful feed as a basis for adequate rations will probably be able to make a reasonable profit during the coming winter. With milk cow numbers now 6 per cent less than the record number a year ago, the six-year expansion in the nation's dairy herds has to a great extent ended. Continued close culling of lower producing cows and the feeding of better rations will further strengthen the dairymen's position, it is believed.

Not since 1917 has the state had a crop as large as the indicated harvest of more than four million tons for 1935, according to reports of A. J. Surratt, state agricultural statistician, Springfield. Feed grains this year are more than double the 1934 crop, and the corn crop, estimated at 74 per cent of normal on August 1, may be nearly twice as large as the 1934 crop. Soybean prospects are good, and the crop is in the making on the largest acreage in the history of Illinois.

Considering the roughage and small grains already harvested and the prospects for those not yet matured, there seems to be no reason for feeding cows inadequate rations this winter, especially if the corn crop makes good, Rhode said.

Equal parts of ground corn and oats along with a liberal allowance of good legume hay or the only roughage makes an excellent ration for milk cows. If soybeans are available, they will furnish the needed protein concentrates. Where both legume hay and plenty of silage or good fodder are available, a satisfactory grain ration may consist of 5 parts ground corn-coe meal, 4 parts ground oats and 1 part ground soybeans.

### Bagworms Arrive To Menace Shade Trees In Illinois

Newest arrivals among insect enemies of Illinois trees this year are bagworms on many evergreen trees as well as on some of the box elders, soft maples, lindens and willows, it is reported by W. P. Flint, chief entomologist for the College of Agriculture, University of Illinois and the Illinois State Natural History Survey.

The worms appear during August in little moveable cocoons hanging from the leaves. They are not actual cocoons but little houses for the worms and give the bagworm its name, Flint explained.

Worms are numerous this summer and are attacking both deciduous and evergreen trees. However, they are more injurious to evergreens since one stripping of them kills them.

While sprays should have been applied earlier in the summer just after the worms were hatched, many of the pests will be killed if a lead and lime spray is thoroughly applied during August. The most satisfactory mixture is made of 1 pound of lead arsenate, 2 pounds of lime and 50 gallons of water. The lime is so thick added to prevent burning of the foliage by water-soluble arsenic in the spray.

During the coming winter further control may be obtained by picking the bags off the smaller trees. The bags should be burned.

The ideal time to spray for bagworms is just after they have hatched. In southern Illinois they begin to hatch about June 1, in the central part of the state June 10 is about the date, while June 20 to 25 is the hatching date in the northern sections.

## Future Meeting Of Cattlemen Is Expected At U. of I.

Based on the unusually large number of Illinois farmers who plan to market a good share of their prospective corn crop in the form of cattle this fall and winter, a record crowd is expected to attend the eighth annual meeting of Illinois beef cattle feeders September 1st at the College of Agriculture, University of Illinois, said H. P. Robbins, head of the animal husbandry department at the college.

Visitors at this year's meeting will have the opportunity to inspect more than 100 head of experimental cattle divided into 17 lots no two of which have been fed exactly the same way, Robbins stated. The chief object of interest will be eight lots of yearling steers which have been furnished daily information during the last seven months in the value of protein concentration, blue grass pasture, corn silage and other feeds in producing choice market cattle.

Another point of interest this year will be the experiments which have indicated that a crop of soft corn properly stored and fed will produce as many pounds of gain as a steer fed on hard corn. This experiment has taken on added significance because of the late corn crop in many sections of the state and the prospects for a considerable amount of soft corn this fall.

Until the new corn crop becomes available, cattle feeders are using to good advantage various combinations of roughages recently threshed on Illinois farms, according to E. T. Robbins, livestock extension specialist of the agricultural college. With favorable cattle prices in prospect, he plans to keep the animals gaining as rapidly as possible and then put them on to finish with the new corn this fall.

Among the combinations showing good results are oats and wheat, oats, wheat and barley, or oats, wheat and corn where corn is available. These grain rations along with good pasture and blue grass, so plentiful in the state this year, have produced good gains and furnish a fairly economical way of keeping cattle gaining until more corn is available, Robbins stated.

Some operators are buying corn at 90 cents a bushel to continue the feeding program which they started in the spring. In cases where cattle fed in this manner have been sold, they have paid a good return on the feed and risk which was involved in the venture.

Cattle feeders are also making plans to conserve all the roughage available for next winter's feeding, since last winter they found that roughage is an economical feed for wintering cattle as well as a good supplement to grain rations where the animals are being fattened for market.

The silo is expected to be the most popular place for the storage of corn fodder and corn stover as well as many other types of roughages, Robbins stated. Pit silos are especially suitable, since they may be constructed at a relatively small cost to take care of the extra amount of roughage crops expected this year.

How to Get the Most from Eggs for Using Extra Eggs

Value of proper flock management and marketing of eggs is practiced by several southern Illinois poultrymen is illustrated by one farmer. That section who has received greater returns and higher profits from his flock this summer than have many of his neighbors, it is reported by H. H. All, poultry extension specialist at the College of Agriculture, University of Illinois.

Because he fed and managed his flock for high production of quality eggs, and also graded the eggs carefully, stored them properly and marketed them on the grade rather than on the bird, this poultryman has this season the summer received 1 cent a dozen, less shipping and handling charges, as compared to his local "count basis" price of 11 cents.

First of all, he has had no losses after the hatching season. Consequently all of the eggs produced by his flock this summer were infertile, and spoilage was held at a low level. The birds were confined and well fed on a ration of grain and mash mixture. The birds were supplied with oyster shell and water. Under this management the flock produced 100 percent of fertile eggs.

Eggs were set in a clean, dry, well-ventilated egg cellar. Good egg cellar cases, flats and fill boxes were used. The egg cellar and consequently were on cool side of the house. In order to keep the eggs from getting too hot and placed a wire-mesh screen over the egg cellar.

In packing eggs for market, the poultryman graded them according to size and sold only the clean eggs. The shells were filled to capacity with fillers were clean, dry and each egg was packed in a separate box. The buyer could tell at a glance what grade of eggs he was getting in the case. If two grades were included in a case, they were packed in separate boxes. All eggs were protected from the sun and heat all during transportation.

Since the farmer's flock of birds were leaving the farm, they could not be vaccinated with any of the new vaccines.

Wilt Disease of Tobacco and Other Plants

Tomato wilt disease has been generally fairly fair this year, but serious wilt is being reported from a section of Illinois according to E. I. Weaver, vegetable gardening specialist at the College of Agriculture, University of Illinois.

It is interesting to note that the disease now, Weaver said, but growers should take warning and look out to prevent this disease when they plant tobacco in the spring. The wilt disease is a serious loss to tobacco in Illinois and many other districts with the exception of leaf cut. It can be prevented only by planting of resistant varieties.

Among the varieties resistant to tobacco wilt are Freedom, Early Redhead, Home, Illinois Pride, Marloby, and Sritchard. The first three of these have been developed at the College of Agriculture, University of Illinois and will be available for the future.

Tobacco wilt is often carried on the soil, but once in the soil it is difficult to live in the soil. The disease is caused by a soil-borne fungus which enters the plant through the roots. The wilt can be spread by the transportation of tobacco plants from one field to another. Soil working, wind, and other factors can also spread the disease. Consequently the possibility of preventing disease by planting tobacco on clean ground is small.

In general, soil sterilization is effective, but it is not a practical method of any field conditions.

Record Hog Weigh Sets New High Mark For 4-H Members

The new world record price of \$1,160 a pound for fat market hogs, which was recently established by an Illinois 4-H boy's pig, sets a new all-time high in achievements of the 4-H farm boys and girls of the state who are enrolled in 4-H pig club work under supervision of their county farm advisers and the extension service of the College of Agriculture, University of Illinois.

The holder of the new world record on fat hog series is Willard Brittin, a 16-year-old 4-H club member of Galesburg, Tazewell county. It was established during one of the night society hog shows at the fair at Illinois State Fair when Willard's 170-pound Berkshire barrow was sold to a local auction company for a total of \$127.60.

All of Willard's 8,000 fellow pig club members in Illinois are being trained in modern and approved methods of breeding, feeding and managing hogs under direction of their county farm advisers, local leaders and the extension service of the agricultural college, but the new price of \$1,160 a pound is expected to stand for some time.

Less than 24 hours ago a tomcat for \$17.00 had been placed in his hands, he had invested \$500 in a pair of Berkshire gilt. With this as a start he hopes to build up a purebred herd of his own and a splendid life on his farm. With the remainder of the money he intends to establish his bank account which will be used to deplete in order to get extra money for his competition at the fair.

Previous to the sale of Willard's pig at \$1,160 a pound, the best mark was \$1.60 and his record that it was 77 cents.

Willard will be a junior in the Williamsville high school this fall and is now in his third year of 4-H club work.

He has two brothers, and his father owns and farms 160 acres of land, specializing in Berkshire hogs and purebred Berkshire cattle.

The record on hogs was the feature of the county fair 4-H club show in which approximately 1,000 of the boys' and girls' 4-H club members of the state competed for a share of the \$17,500 prize money.

-3-

Tomato Juice Can Be Served In The Home Kitchen

Tomato juice, the increasingly popular health drink, may be made in the home kitchen this fall especially since the Illinois tomato crop is showing a fairly good yield of desirable fruit, said Glenn A. Emerson, foods extension specialist at the College of Agriculture, University of Illinois.

The juice is extracted by pre-cooking the tomatoes only until soft, at a temperature of from 170 to 180 degrees, or slightly below boiling if a thermometer is not available. The hot, softened tomatoes are then cut through a conical strainer. Skins should be removed before the tomatoes are cooked.

The juice should be reheated once after it has been cut through the strainer, poured into sterilized containers and then sealed and processed in a water bath for 10 minutes. Salt may be added if desired in the preparation of one-half gallon tomato juice to the quart. It is more desirable to add other seasonings just before the juice is used.

Only a small amount of tomatoes should be worked up at a time, and either the cooked tomatoes nor the juice should be allowed to stand any longer than is absolutely necessary during the processing, since exposure to air will destroy the vitamins as well as the health-giving vitamins. It is desirable to use the fruit as soon as it is available.

After the tomato juice has been prepared, it should be labeled and stored in a cool, dark place.

## Record Soybean Crop Brings Danger Of Soft-Pork Loss

A record crop of soybeans in Illinois this year will mean heavy losses from soft pork if farmers attempt to use the whole soybeans for fattening hogs, according to a warning by Prof. Albert Bull, associate chief in meats at the College of Agriculture, University of Illinois.

While whole soybeans cause soft, flabby pork that is of inferior market quality, soybean oil meal used as a supplement for corn in hog rations will make firm pork, Prof. Bull points out. At the same time soybean oil meal will produce faster and more economical gains than can be obtained with whole beans.

It is suggested that farmers trade any whole beans which they would feed to hogs for soybean oil meal, thus securing a valuable protein supplement for their corn and at the same time avoiding the risk of soft pork losses.

It is to the advantage and profit of farmers to do everything possible to avoid soft pork, since neither shippers, feeders, meat packers, exporters nor consumers want such meat, Prof. Bull said. The soft pork problem may become so serious that "soft" hogs will have to be discriminated against. A few loads of such hogs from any one shipping point would be sufficient to give that territory a reputation for inferior pork, with the subsequent danger of price penalties to producers.

An added inducement for using soybean oil meal instead of whole soybeans is the fact that it produces just as good gains as turkey and linseed meal and at present prices is more economical than these two supplements, Prof. Bull said. Experiments at the U. of I. College of Agriculture have shown that 14 pounds of soybean oil meal and four pounds of alfalfa meal are equal to the standard corn belt supplement of eight pounds of turkey, four pounds of linseed meal and four pounds of alfalfa meal. At present prices the soybean oil meal would be the more economical feed.

Other experiments in Illinois, Indiana and Ohio have demonstrated that soybean oil meal used to balance corn produces 15 to 20 per cent more rapid gains than whole soybeans, shortens the fattening period by two months, and results in 25 per cent of the feed and makes firm carcasses of high quality, Prof. Bull reports.

Corn and soybean oil meal fed at the rate of one bushel of corn and nine pounds of soybean oil meal with alfalfa meal makes a good ration for fattening hogs. However, a mineral mixture should always be fed when soybean oil meal is used in hog rations. A good home-made one can be mixed from 3 parts ground limestone, 2 parts steamed bone meal and 1 part salt.

Cooperation among farmers in avoiding the feeding of whole soybeans will protect their shipping point against getting a reputation for soft pork, Prof. Bull pointed out. At present market prices of soybeans and soybean oil meal 15 pounds of firm pork can be produced quicker and cheaper than 15 pounds of soft pork. Furthermore, the reputation of the community for producing good hogs will add much to the profitability of future operations, he said.

12-Year-Old Soil Plan Paying Dividends On Fulton Farm

Twelve years of rebuilding and maintaining the fertility of his 250-acre farm through the use of limestone and legumes are now paying dividends in the form of feed, better balanced rotations and reduced costs of production for L. F. Randolph, of Fulton county, it is reported by C. M. Linsley, soils extension specialist of the College of Agriculture, University of Illinois. Randolph has limed about 200 of the 250 acres of his farm, and the rest probably will be limed within the next two years.

This year 20 acres of sweet clover on limed land pastured 25 head of cattle, 20 sows with 125 pigs and six horses. The pasture could have carried almost double that number of livestock, Linsley believes.

This same 20 acres, once considered the poorest land on the farm, furnished 10 loads of sweet clover hay and plenty of pasture for 25 cattle and six horses during the drouth last summer. The clover came up as a volunteer crop last spring and took a poor crop of oats. Its excellent growth in spite of the drouth was possible because limestone had been used to sweeten the soil, Randolph believes.

Another proof of the value of limestone is shown by the fact that corn yielded 48 to 55 bushels to the acre on limed land at Randolph's farm last year, Linsley stated.

"Nothing can beat lime and sweet clover for putting life in the soil," declares this Fulton county farmer. He has found limestone profitable, since it has enabled him to maintain soil fertility and obtain better than average hay and pasture crops from legumes.

During the past two years shifts from surplus grain crops to alfalfa and clover have been much easier for Randolph because much of his soil is limed and grows these soil-building crops readily, said Linsley.

Randolph's farm is an example of hundreds of Illinois farms on which soil fertility and earning power have been maintained and increased by the use of limestone. Many farmers have found that acid soil must be limed and clovers grown regularly in the rotation if the land is to continue earning enough to support the farm family.

When the common practice of grain cropping is followed, fertility of the soil will be depleted and crop yields will decrease year by year. Eventually a stage of soil depletion may be reached when the income from poor crops will not furnish a living for the farmer. When conditions get this bad, it will be too late to make any investments in soil improvement, Linsley declared. Many Illinois farms are not far from this stage now, he said. The longer liming is postponed, the more difficult it will be to finance this soil improvement work.

-M-

Good Feed Supply Ends Need For Late Alfalfa Cutting

With supplies of feed, especially good roughage, plentiful in Illinois this year, there is no necessity of injuring alfalfa stands by late cutting, declared J. J. Pieper, crop production specialist at the College of Agriculture, University of Illinois.

To avoid winter injury to their alfalfa, Illinois farmers should not cut hay crops later than six weeks before the first killing frost. For northern Illinois the average date for the first killing frost is about October 16, which means that alfalfa should not be cut later than the first week of September.

In central sections of the state killing frosts occur a few days later, averaging about October 18 to 19. They may be expected in the southern third of Illinois about October 24. Frosts have killed vegetation in all of these sections during September, occurring as early as September 14 in the northern and southern sections and on September 16 in the central section. However, such early frosts are the exception, and most alfalfa will be safe if not cut after the first week in September, Pieper said.

-M-

Soft-Corn Cask - Luring Farmers To Temporary Silos

Possibilities of a large amount of soft corn in Illinois this fall have turned farmers to preparations for temporary fence silos and other emergency means of storing as much of the crop as possible, according to the agricultural engineering department, College of Agriculture, University of Illinois.

While corn is making rapid growth, there is danger that frost will catch some of the crop before maturity, it is shown in reports coming to J. J. Pieper, crops specialist at the college. The fence silo offers a economical and satisfactory way of preserving this soft corn for winter use.

Most common among the temporary fence silos are those constructed of the familiar racket, or snow, fence. Wood wire fencing is also used to some extent. The fence is set up in a circle of the desired diameter after the ground has been leveled for the base. The inside is lined with heavy building paper and filled to within about six inches of the top before the second section is fastened on top, said W. A. Foster, chief in rural architecture at the college.

Diameter and height are governed by the capacity desired, although a height of not more than the diameter will ensure greater stability. A silo 10 feet in diameter will hold approximately 10 tons of silage, while a 20-foot silo will hold about 46 tons. A complete table of sizes and capacities, as well as instructions for building fence silos and box silos are available at the agricultural engineering department of the college.

This information gives details for determining the size of site needed, laying out the ground, constructing the silo, filling it and preparing the ensilage for better keeping.

-M-

Silos Make Good Storage For Extra Supplies Of Hay

Since hay mows are already bulging with good legume hay, silos probably will be pressed into the unusual service of furnishing storage space for much of the additional hay crops being raised in Illinois this year, said W. B. Nevens, associate chief in dairy cattle feeding at the College of Agriculture, University of Illinois.

Contrary to the popular opinion, most legume hays make excellent silage for dairy cows if handled in the right way, Nevens declared. Alfalfa, soybeans and the various clovers, all of which are growing in abundance in the state this year, can be made into palatable, nutritious ensilage.

The only difficulty with legumes as silage is that they will develop a strong, unpleasant odor and become unpalatable if put into the silo too green. This is caused by deterioration of the large amount of protein in such crops. This condition not only reduces the feeding value of the ensilage but also is likely to taint the milk, since the odor will pervade the entire barn. Some of the taint also is carried to the milk from the silage eaten by the cows.

Allowing the legume hay to wilt and dry out after it is cut will help prevent the unpleasant odor and taste. The surest method of preventing the development of these lowering qualities, however, is to mix fairly green corn with the legumes half-and-half by weight or not less than one load of green corn to two loads of legumes. The additional sugar in the corn causes an acid to form, thus preventing deterioration of the protein and the development of the bad taste and smell, Nevens explained.

Another method which may be used where green corn is not available is to mix black strap or sugar beet molasses with the hay at the rate of 1 to 2 per cent, or 10 to 40 pounds to the ton.

## Address of the Editor, The Extension Messenger

I am pleased to receive your letter of the 27th and to hear that you are interested in the Extension Messenger. The purpose of this publication is to provide timely information to farm advisers and others who are interested in the work of the Agricultural College, Experiment Station, and Extension Service.

The Extension Messenger is published monthly, except during the summer months when it is published bi-weekly. It contains articles on a wide variety of subjects, including crop production, soil fertility, animal husbandry, and farm management. The articles are written by experts in their respective fields and are intended to provide practical information that can be used on the farm.

The Extension Messenger is a free publication and is sent to all farm advisers and other interested parties. If you are not a farm adviser and would like to receive a copy, you may apply for a subscription. The subscription fee is \$1.00 per year in advance.

The Extension Messenger is published by the Agricultural College, University of Illinois, Urbana, Illinois. It is printed by the University of Illinois Press. The Editor of the Extension Messenger is Dr. H. W. Morrow, Director of the Extension Service.

The Extension Messenger is published by the Agricultural College, University of Illinois, Urbana, Illinois. It is printed by the University of Illinois Press. The Editor of the Extension Messenger is Dr. H. W. Morrow, Director of the Extension Service.

Well-Ventilated Crib Will Kill Corn Earworm

Since most of the Illinois corn crop of an estimated 1,000,000 bushels will be late in maturing, cribs which not only protect the grain but also give it plenty of ventilation for drying and curing will save next spring the heavy losses, it is believed by W. A. Foster, rural architect at the College of Agriculture, University of Illinois.

Familiar to most of the farmers of the State is the fact that in 1917 these ears will be drying and curing in the field, Foster said. In addition to a lack of air circulation, the ears will be subject to the grain and stalk borers, weevils, rats, mice and other destructive insects of the corn.

The provisions for the construction of cribs are, direct from the Agricultural Credit Corporation, as follows: "The crib should be constructed on a level and to be raised at least 4 feet above the ground to protect it from the soil."

In figuring on the cost of a crib, the farmer can base his estimate on the fact that a crib 10 feet wide and 10 feet high will hold 100 bushels of corn. A small crib 6 feet wide and 6 feet high will hold 36 bushels of corn. A crib 12 feet wide and 12 feet high will hold 144 bushels of corn.

Since it is not possible to have a crib raised above the ground, a scatter bed or a "straw bed" is advised, especially for the farmer who is just starting out. The crib should be built on the selected site to be used. Later on, when a road or driveway is built, a driveway between a small crib and a larger one will be of great value and the road should be built.

The crib should be built on a level and to be raised above the ground. The construction of a crib is as follows: "The crib should be built on a level and to be raised above the ground. The crib should be built on the selected site to be used. Later on, when a road or driveway is built, a driveway between a small crib and a larger one will be of great value and the road should be built."

Details concerning the construction of cribs for grain and corn can be obtained from the department of agriculture, Bureau of Entomology and Plant Quarantine.

-16-

How Insect Proofing of Cell Crib Will Kill Corn Earworm

For the farmer's sake, it is suggested that the following instructions be made to be certain that the crib will be well protected from the earworm. This fall, it is suggested by W. A. Foster, rural architect at the College of Agriculture, University of Illinois.

In addition, every ear of corn should be dried and cured in a well-ventilated crib. The crib should be built on a level and to be raised above the ground. The crib should be built on the selected site to be used. Later on, when a road or driveway is built, a driveway between a small crib and a larger one will be of great value and the road should be built.

Small Grains Make Valuable Erosion-Preventing Crop

Small grains are becoming of increasing importance in Illinois this year because of their ability to hold soil and their ability to fit into the agricultural program for grain crops, according to J. J. Pieper, crops specialist at the University of Illinois, Urbana. Nor have these new possibilities been established for small grain pasture as a feed saver and economical winter feed.

Wheat, barley and rye make excellent fall pasture. Winter barley has a special favor in the southern section of the state, and can be planted with the other grains without danger of injury to the soil. It can be cut at the stage four to six weeks after planting and will stand over the winter and into the early winter. October 1 will be the best time to plant small grains this year, Pieper said.

Although small grains are good crops if they are used as nurse crops for other crops, they are also good pastures. Pasture mixtures which are made up of fall planted small grain and the small grain. The grain will furnish feed for the winter, while the grasses will become available later next year. Spring planted small grains will furnish feed for the small grain next year without the need for a winter cover crop, Pieper declared.

Pasture mixtures which are made up of fall planted timothy, brome grass, red top and clover. Other mixtures which will be planted in most sections of Illinois include timothy, brome grass, red top, alsike and white clover in addition to the small grain.

Winter planted small grains requiring that new areas be planted in substitution of the old, will be a more convenient and effective method of maintaining the soil. The small grains will help hold the soil and minimize the loss of soil to the water table. The addition of the pasture crop will also help to reduce the erosion feature of the crop.

When farmers intend to use small grains for use as pasture crops on acreage that is under contract, they should consult their county or community committee and their insurance companies will conform to terms of their contracts.

Efficient Method of Applying Limestone Lowers Cost

More efficient and cheaper methods of hauling and spreading limestone, such as those developed in Winnebago county last spring, have enabled Illinois farmers to make more efficient use of limestone, it is believed by C. M. Hinsley, soils extension specialist at the College of Agriculture, University of Illinois.

Under the new method, the use followed by E. E. Porter, of Winnebago county, the limestone is moved by a tractor to the crusher where it is pulverized and then hauled to the field.

This method is efficient enough to allow five-ton trucks to back under the dust and limestone while travelling, Hinsley said. The trucks, of the power type, are equipped with special attachments. Consequently, the limestone is transported from the quarry to the field where it is spread by operating the spreader which is attached to the truck as the truck is driven across the field. When the truck is allowed, the limestone is dumped from the trucks into the field where it is spread by tractors. By this method all of the usual difficulties are eliminated.

## Milestone Is Set In Spread Of Farm Management Service

A milestone in the spread of farm management services has been set, with the holding of the "10 year high" meeting at Urbana of the College of Agriculture, University of Illinois, according to Dr. H. H. Cole, head of the department of agricultural economics.

Ten years of progress in the college's farm business management service project were summarized and discussed by several hundred farmers attending the meeting. Sixty-three farmers who had met regularly during the ten consecutive years of the project were called on to testify by Dr. H. H. Cole, head of the department of agriculture.

This is the first meeting held for farmers, however, to see the results in cooperation with their farm advisers and the extension and college. The farm business management service, since its beginning in 1927, has been in 15 counties and is now being extended to 25. In the development of this present service, are enrolled, respectively, 100 and 150 farmers in the two counties.

Through their own and farmers have found out how well they are running their farms as compared with their neighboring farmers and they have been wised in applying to their own farms the practices that have proved profitable on other farms of a similar type.

One of the outstanding results of the ten year meeting has been a seven-point program for good farming. This has been built up by the college through a half century of experimental work and is being put into practice by the farmers who have kept during the past decade of years and the accounts summarized during the last ten years in the farm business management service project.

The seven points of the recipe are: (1) plan a rotation of crops and a good field arrangement; (2) keep the kinds and amounts of livestock that are well suited to the farm, the farmer and the market; (3) realize high yields of crops; (4) realize good returns from feed for livestock; (5) keep the costs low in proportion to income; (6) keep power, farm machinery and livestock equipment costs low in proportion to income; and (7) keep building and home costs low in proportion to income.

Among the 67 farmers who have met regularly through the ten years of the project, the one farmer whose farm excelled in all seven of these factors had an average annual net income of \$4,500 during each of the ten years. The six farmers whose farms excelled in six of the seven factors had an average annual net income of \$2,891.

Farms strong in five of the seven factors had an average annual net income of \$2,000; those strong in four factors earned an average annual net income of \$1,140; those strong in three, \$1,915, and those strong in only two factors, \$1,000. Farms which excelled only in one or none of the seven factors had an average annual net income of only \$965 for each of the ten years.

Some farms not making high incomes at the present time are building up the productivity of a badly-skeletoned soil and getting high-producing livestock well established. With good farming practices these farmers will be able to raise their earnings materially in years to come.

Erosion Control Will Be Aided By New Soil Studies

Control of soil erosion on the lands of acres of Illinois farm land is expected to be aided through studies conducted by the College of Agriculture, University of Illinois, to find the best ways to control rainfall on different soil types.

Samples of soil from significant soil types have been "planted" on the college farm as a basis for the studies. These include soils from as far south as Madison county, as far north as Lee county, as far west as Hancock county and from other places within this general area.

By measuring the amount of surface run-off from these soils and the rate of water percolating through them, the investigators hope to secure information needed in the development of more effective erosion control methods in the state. Findings made in the college's soil survey show that there are more than 4 million acres of Illinois farmland that are subject to destructive erosion and should never be farmed, more than a million additional acres that are subject to serious erosion and suitable only for grazing. Present erosion control methods are necessary to maintain the productivity of the land.

Only one method was used to prevent the rain all on these different soils is it possible to work out the best erosion control methods, it was pointed out by F. S. Steffler, assistant professor of soil physics in charge of the new studies.

The college method of the studies were done by forcing hollow cylinders, 36 inches in diameter and 4 inches long, into the soil. The cylinders with the soil cores in them were left in place and brought back to the college where they were set up so that water falling on the surface is free to escape as run-off or by percolating through the soil.

Both the run-off and the percolation are measured. A rain gauge near the set-up records total precipitation. Thus the disposal of the water falling on the surface can be calculated. The soil test has not been in operation long enough for any definite conclusions to be drawn. It is hoped that within a relatively short time accurate information may be available as a help in meeting soil erosion problems.

-M-

Water As Well As Feed Needed For Production Of Eggs

It takes water as well as feed to produce eggs, according to H. H. Alp, poultry extension specialist at the College of Agriculture, University of Illinois. This means that since hens have very little water storage capacity, water must be supplied at all times if the flock owner expects to take advantage of higher egg prices in winter's set.

Approximately nine pounds of water are required for each dozen eggs laid, according to records of daily water intake of 60 White Leghorn pullets at the college over a period of four weeks.

Another significant fact brought out by the trials was that egg production increased almost in direct proportion to increased consumption of water. During the first week the hens drank approximately 2.16 pounds of water each. Egg production during the same week averaged 2.99 eggs to the hen.

During the last week of the trials water consumption averaged 3.08 pounds, nearly 44 per cent of the first week's average. Egg production during the last week averaged 4.19 eggs, or approximately 140 per cent of the first week's production. These figures indicate that where the ration is adequate, plenty of drinking water will help boost the laying efficiency of hens, Alp stated.

-M-

Low Profits In View If Feeders Use Sound Methods

Five to six lamb carcasses are sold in the State of Illinois for a profit of \$1.00. It is found that a fair profit from a feeder lamb is \$1.00. The state of Illinois follows the right to give and management with it, says W. G. Karlade, sheep-raising man at the College of Agriculture, University of Illinois.

A slaughterer of 1928 lamb carcasses to date has reduced the number that will be sold in the State of Illinois. This indicates that conditions during the winter of 1928 were not so good. Another factor contributing to the low value of the lamb is that in the winter feeding conditions have been such that western growers can get a higher price for their lambs. Instead of feeding Illinois farmers will have the advantage of identifying the quality of their local feed. Karlade stated, "A good feeder lamb will sell for half as much as in 1928 if added."

All these factors indicate that western feeder lamb carcasses are profitable if they are bought in the winter months. Since they have been in transit from one place to another, the lambs are likely to be weak when they arrive. Consequently the check on the condition of the lambs is given and the lambs, given some time to reach the farm.

Plentiful water and good grass, plenty of water and a small amount of salt is an important factor in the winter months after the lambs reach the farm. They should be placed in a dry and rest place where there is shelter, Karlade said. This early care is highly important, since many of the lambs, weakened by the trip, may come to such a stage as they reach the farm unless they are handled carefully.

Clean, well-ventilated shelter of sufficient capacity to house the lambs without crowding will contribute to a healthy fast-gaining flock. The shelter, however, should not be so tight that lambs will not be able to get in the open during cold, wet weather. Plenty of water and salt should be available at all times.

The lambs should be transferred gradually from roughness to concentrated feeds to avoid losses from digestive disturbances. Even after the lambs are on full feed, plenty of available roughage will be needed to guard against over-eating of concentrates, according to Karlade. Detailed information on the care and feeding of lambs is available in circular No. 41, "Feeding Lambs on Illinois Farms," available at the college.

Butter Imports Show Rapid Decline Since Last Spring

Imports of butter are falling off in foreign butter imports had accompanied increased domestic production and decreased consumption this year, according to reports received by the College of Agriculture, University of Illinois, from the U. S. Bureau of Agricultural Economics. The New Zealand butter has been imported since April, it is stated in the report. European imports amounted only to 17,200 tons in July of this year as compared to 1,447,000 in June of 1928, a 98.4 per cent decrease.

While imports have been decreasing, domestic production has been increasing. June butter production this year amounted to approximately 137 million pounds as compared to 127 million last year. Consumption, however, decreased from 147 million pounds in June, 1924, to 138 million in the same month this year, the report states.

Under the February London and New York price conditions, importers of butter at the 14 cent import tariff on each pound of butter brought into the country would not have a margin of profit. However, as the spread between New York and London prices decreased, the margin disappeared and imports declined.

## Soft-Corn Silage Best Way To Save Corn Hit By Frost

Any of the 7<sup>1</sup> million acres of Illinois corn crop which may be caught by threatened frost loss this fall can be utilized by being snapped, husked and all, and made into soft-corn silage, according to H. E. Bask, head of animal husbandry at the College of Agriculture, University of Illinois.

There have been six soft-corn years since 1919, and the college has worked out the best methods of salvaging the grain by running extensive feeding tests.

Corn that has been frost-killed before maturity usually is too high in moisture content to keep if placed in a crib. In fact, a moisture content above 60 per cent is too high for cricking corn safely, Bask states. Feeding trials such as soft-corn years as 1924 have shown that soft-corn harvest contains less than 50 per cent moisture.

Running the ensilage corn through the ensilage cutter and cutting it into silage helps to conserve much of the food value of the immature grain, conserve a storage space, lightens the feeding work during the winter and is the most satisfactory way of curing soft corn, according to tests made at the college.

During the tests, ensilage of soft-corn yielded in this way produced 285 pounds of gain on a herd of steers. The next best method to this was to cut up the silage into gain to the acre where the soft-corn was stored in the shock and fed from the shocks as needed during the winter.

When the corn was allowed to stand in the field and hauled as needed, only 155 pounds of gain on beef steers. Pasturing proved to be the poorest method with each acre of soft-corn producing a gain of only 17 pounds when the steers were allowed to run in the field and eat the corn from the stalks or ground.

None of the methods tested showed gain in value with hogs, although here following steers fed silage of corn did the best, making about 4 pounds total gain per acre of corn fed in this manner.

## State Contest In Corn And Poultry Judging In Oct. 1

Outstanding of the best judges from among the 1, 0 Illinois farm boys and girls who are enrolled in 4-H corn and poultry projects will compete for the state championship judging honors in these two lines of work in a contest to be held at the College of Agriculture, University of Illinois, October 1, it is announced by E. I. Pilchard, boys' club specialist.

This year the poultry judges will be required to select five classes of four specimens each, Pilchard says. Four classes must be selected by the American standard of perfection rules and the other four according to local or national conditions. Breeds which may be used will include Barred Plymouth Rocks, Rhode Island Reds, White Wyandottes and White Leghorns.

The corn judges will be required to select three classes of corn consisting of four 16-ear samples each. The classes will include two samples of white and yellow corn and one sample of white and yellow.

Tests Show Safe Methods Of Meeting Spray Tolerance

With a large crop of apples to be moved in Illinois this fall and lower spray residue tolerance effect, growers can protect themselves by following successful methods of spray removal worked out in experiments by the College of Agriculture, University of Illinois, according to fruit specialists of the institution.

Lead tolerance has been reduced by law to .018 grains to each pound of fruit during 1937. The original tolerance remains at .01 grains. If the lead tolerance is met the arsenic tolerance almost invariably will be met also, it is stated by W. A. Ruth, chief in botanical pathology, and K. J. Kadow, associate pathologist.

The tolerance specified by the government must be met before the apples can be sold. Shipments which do not meet the specifications are liable to seizure. Because of this regulation the consumer may rest assured that there is no danger of spraying residue from fruit that has reached the market.

Since the tolerance is relatively low, growers are faced with the problem of removing the spray residue without injuring the fruit. The process consists in washing the apples, either in hydrochloric acid or sodium silicate followed by acid. Usually one acid bath is sufficient. Acid injury may be caused by too high a concentration of acid, too strong a solution or too long an exposure of the apples to the solution, Ruth and Kadow stated.

Variety and condition of the apples also may influence the injury. Apples picked prematurely or small are more sensitive to the treatment. The safest procedure is to run tests with the different varieties of fruit and vary the methods of washing until the injury is reduced to the smallest possible degree.

Acid solution for best result should be made up with about 1½ per cent actual acid and held at a temperature slightly above 100 degrees Fahrenheit. Acid injury shows up in minute or irregularly at the calyx end of the apple.

Silicate injury is caused by the lack of thorough rinsing after the apples have been washed in a dilute silicate. Such injury is indicated by a round, burned area at the calyx end of the apple and in times cracking similar to that caused by acid.

It is suggested to analyze a sample of the apples before washing to determine tentatively the concentration of the solution needed. The apples should be analyzed after the washing to insure the residue is down to government specifications.

Detailed information on washing and testing apples is available from the horticultural department at the college.

-M-

New-Type Cotton Eases The School Clothes Problem

Cotton fabrics that have anti-crease qualities and resemble wool to the extent that they may be substituted satisfactorily in many cases are now available to simplify the winter school clothing problem for many Illinois mothers, according to Miss Edna P. Gray, clothing-extension specialist at the College of Agriculture, University of Illinois.

With these developments cotton is destined to become more popular as a fabric for school clothing, since it possesses many other qualities, both from the economic and comfort standpoints, which adapt it to the school child's needs, Miss Gray believes.

Information on the buying and construction of school and play clothing is available at the home-economics department of the college. In addition, three recent U.S.D.A. publications, No. 52, 54 and 80, describing the construction of suits for boys, dresses for girls and play suits, are available at a small cost at Washington, D. C.

-M-

Ten-Year Records Fix Value of Good Farming Methods

A new price tag can now be put on good farm management methods as a result of ten years of records which Illinois farmers have kept by the farm bureau-farm management service project of the College of Agriculture, University of Illinois, according to Prof. M. E. Mosher, of the department of agricultural economics.

The figure on the price tag, or the value of good farm management, may be a surprise to those who have underestimated the worth of good crop yields, livestock efficiency and other recommended practices in safeguarding farm earnings and promoting general farm prosperity. Prof. Mosher pointed out.

Records kept by 57 farmers who have been enrolled throughout the ten years of the farm bureau-farm management service project form the basis for the new price tag. Fifty-seven of these farmers occupied the same farms during the ten years and otherwise operated their land so that it was possible to make direct comparisons between them.

Ten of these 57 farms made more marked improvements in their farm management methods than others during the ten years of the project. However, during 1931, 1932 and 1937, the first three years of the project, before the improved farm management began to make itself felt, these ten farms which had an average annual income of \$1,195 less than the average for the whole 57 farms.

During 1933, 1934 and 1935, the last three years in the ten-year period, each of these ten farms on which the farm management methods were improved earned an average annual net income of \$325 more than the average for the whole 57 farms.

These farmers improved their position, Prof. Mosher explained, by using their records and accounts to find out how well they were running their farms as compared with other crop-raising farmers. They also applied practices that had been proved in the records to be profitable on other farms of a similar type to theirs.

Thus in ten years these farmers, as a group, advanced from a position far behind the average for all farms in the project to a position well ahead of the average.

Fall Festival To Showcase Watermelon From All States

Illinois' fame as a watermelon state will be proclaimed in the first annual fall watermelon festival at Havana, September 25 to 27, according to L. A. Jones, vegetable gardening extension specialist at the College of Agriculture, University of Illinois.

Some of the state's finest watermelons will be "on display" at this show. The Cuban Queen, recently introduced into Illinois by the extension service of the Agricultural College, will be a featured variety.

The festival, supervised by the Pinckney Valley Watermelon Growers' Association, is the first of its kind in our state and was originated to improve the watermelon growing industry in Illinois, an enterprise which produces annually over 100,000,000 worth of fruit.

Melon growers managing the festival plan to appeal not only to the specialist also to the "appetites" of visiting melon fanciers, connoisseurs. They expect to bring 2,000 of their finest melons into quarters to be given to visitors as evidence of the quality of their product.

Varieties of melons which will be on display will include the Cuban Queen which is gaining rapidly in popularity in the state, as well as the older standard varieties such as Dixie Belle, Tom Watson and Flashing West.

Another feature of this colorful show will be the growing of the watermelon queen. The queen-to-be and her two ladies-in-waiting will be selected from among association members announced during the festival.

## Erosion Problem On Three Fronts

Farmers working to check soil losses on more than 19 million acres are attacking the problem from three different fronts. The erosion extension specialist coordinator at the University of Illinois. These are: mechanical control, vegetative control and good management.

Mechanical control includes properly constructed terraces, gully control and check dams. Terraces, carefully maintained, help to prevent sheet erosion. If gullies are already formed, check dams and other structures help to catch soil to be deposited rather than carried away,

and help to filter water, allowing much of it to be absorbed into the soil and erosion. Such furrows are particularly adapted to the hilly areas of the state.

Vegetative control methods, such cover crops as wheat, rye, and clover, are effective in controlling erosion. Experiments have shown that soil is lost from fields growing good stands of cover crops at a much slower rate. Permanent vegetation, where it is adapted to the soil, is the most effective means of preventing soil washing. Alfalfa and clover are good crops for erosion control, Buckardt said. Where the soil is sandy, trees are superior to grass and hay crops.

In the case of erosion control, crop rotations, controlled grazing, and other special practices are considered the most important. Legumes increase the organic matter content, thus helping to prevent soil washing. Controlled grazing prevents the surface from being eroded by heavy trampling, while the use of special practices such as contour plowing, meet special problems on the individual farms or fields.

The college which contain valuable information on various erosion control methods include a mimeographed leaflet, "Grasses and Legumes for Erosion Control" and Circular No. 290, "Saving Soil by Use of Mangum

Cattle Malady Being Suppressed By Testing Of Herds

Costly losses from Bang's disease of cattle have been kept to a minimum by the removal of animals infected with the malady from the herd. A federal eradication program during the year ending March 31, 1935, resulted in the testing of 300,000 cattle by the College of Agriculture, University of Illinois, through the extension service. More than 70,500 cattle were found to be free of the disease as a result of the effort to weed out diseased stock.

Illinois dairymen get more than one-third of their cash income from milk, with an average yield of 100,000 pounds of milk in a year like 1934, and Bang's disease is a serious menace to the industry. It is a contagious breed-  
ing disease.

Dr. J. H. Graham, who has been made in the federal eradication program, states that the disease is a serious menace to the industry. For the men who are cooperating with the eradication program, the disease has been a problem for 11 years ago, according to Dr. Robert L. Smith, who is in charge of the eradication program at the college. His records show that the disease has been a problem for 11 years ago.

The eradication program in 1934 has materially speeded up the removal of diseased stock from the herd, according to Dr. Graham. Under this program, the disease has been a problem for 11 years ago, according to Dr. Robert L. Smith, who is in charge of the eradication program at the college. His records show that the disease has been a problem for 11 years ago.

During the year ending March 31, 1935, the United States during the year ending March 31, 1935, the Federal Government has been a problem for 11 years ago, according to Dr. Robert L. Smith, who is in charge of the eradication program at the college. His records show that the disease has been a problem for 11 years ago.

Beans As A New Source Of Food

Beans are fast becoming a new source of food, as stated in a mimeographed circular published by the University of Illinois. As a revised edition of the circular is being prepared, the current publication contains many new varieties of beans.

The circular was prepared by Dr. J. H. Woodruff, associate chief in foods in the department of the college. That department has been conducting experiments in the growing of beans since the crop first became significant in Illinois. At present more than 100 varieties of vegetable type beans are being tested.

The beans are of high quality, principally to their high protein content and the value obtained in the rich soybean oil, according to the circular. They are also high in vitamin B content. Compared with other vegetables, they are high in such minerals as calcium, phosphorus and iron.

The beans and flour made from them contain a relatively small amount of fat. They are much lower in carbohydrates than other dry beans. They are often used in diabetic diets.

The beans are a valuable source of required nutrients, but they are especially valuable when combined with other vegetables or dairy products. The circular describes the various dishes.

## White Snakeroot Poisoning—To Losses Of Livestock

White snakeroot poisoning of livestock, such as have occurred on several farms in Illinois, is a puzzling problem only because many farmers are ignorant of the cause. In their pastures, according to a mimeographed circular of the College of Agriculture, University of Illinois, "White Snakeroot Poisoning of Animals," was prepared by Dr. Robert C. Anderson, associate chief of the Illinois Experiment Station, and Dr. J. J. Pieper, associate chief of the Illinois Experiment Station, are two of the most troublesome poisons responsible for cases of livestock poisoning. The plants are resistant to white snakeroot, while lactating cows can, with comparative safety, eat the root which would be fatal to steers or dry cows. Black Angus cows are particularly susceptible to alsike clover. In the case of Hampshire hogs, the plant is fatal. Many of them do and, consequently, treatment for stricken animals. Consequently, the best method of preventing such plants, according to the circular, is to remove them from the pastures.

## Winter Drought Is Main Cause Of Oak Trees Dying

The main cause of oak trees being reported in Illinois this fall is the winter drought and the several successive dry seasons preceding it. Dr. C. D. Loomis, tree disease specialist with the Illinois State Forestry Department, working with the College of Agriculture, University of Illinois, reports that during these seasons, and especially in 1934, the supply of moisture in the soil was not maintained and many of the feeding roots of the trees were killed. The conditions produced abundant foliage which could not be supported by the food and water by the drought-weakened root systems, and the foliage and limbs have died, causing conditions known as "winter kill" as well as complete death of some trees. The best method of preventing winter drought injury is to maintain the trees in a vigorous condition by the removal of all dead or diseased wood. While the trees are in the wood lots and forestry plantings, the dead and

Good Season To Clear Up Mystery Of Apple Varieties

This is the year when the mystery of the many unknown and unidentified varieties of apples growing in Illinois orchards could be cleared up if growers were encouraged in sending in specimens for identification, according to R. L. McMunn, chief of the division, College of Agriculture, University of Illinois.

The crop of apples borne so well and so generally that the state's estimated crop for 1935, McMunn said, is almost three times the 1934 crop and considerably more than the yearly average of 4,545,000 bushels, he pointed out. Some specimens for identification are from orchards planted as many as 30 or 35 years ago.

However, there is something more than a sentimental reason why orchardists desire the identification of all varieties with which they are unfamiliar, McMunn said. Apples placed on the market must be labeled with the correct variety name or as "variety unknown." With their trees bearing better than usual this year, growers have an incentive to identify hitherto unknown varieties.

Unfortunately many of the specimens being sent in for identification are coming in in damaged condition or with tags mixed, making accurate naming almost impossible, McMunn said.

Apples sent in for identification should be mature, free from disease and insect injury and of average size and color for the variety. Each specimen should be wrapped individually or placed in a sack with the number written on the sack. Tags tied to the sacks often are lost in shipment, since stems may fall off. Records should be kept of the specimens sent to the horticulture office.

Properly wrapped and tagged fruit should be packed in strong containers to prevent crushing in transit. Cylinder-shaped bottle mailing cartons are satisfactory for small amounts. For larger amounts any good, strong carton will be suitable, McMunn said. The package should be stamped "perishable."

A letter stating that identifications are desired and giving the name and address of the sender should accompany the package. However the letter must be in plain English and stamped with the regular letter postage unless the package of specimens is being sent first class. The specimens should be sent to the department of horticulture, College of Agriculture, University of Illinois.

Neglect Is Worse Cause Of Heavy Rural Fire Losses

Negligence is largely responsible for an annual fire loss of approximately \$10,000,000 on Illinois farms, or the equivalent of one farmstead each week in the year between June 1 and June 30, according to W. A. Foster, rural architect in the College of Agriculture, University of Illinois. For the nation as a whole rural fire losses totaled \$100,000,000 and 3,500 lives in 1934, he reported.

These tremendous losses can largely be prevented through careful and frequent cleaning on the danger points in buildings, cleaning up of premises and greater care in handling fires both in the stove and for such outside work as trash burning or heating in brick or vats.

Among the fire hazards which may be found around the farmstead are dry grass, fallen leaves or piles of old papers or rags stacked in the corner of some buildings. A badly worn roof often constitutes a fire risk, since the shingles are loose and splintered, thus giving sparks from the chimney a better opportunity to start a fire. Roofs should be inspected for possible cracks in the mortar, Foster said. Electric wires should not only be properly installed but also should be large enough to carry the peak current consumption of the circuit without overloading.

How to Grow a Good Crop of Corn in Illinois

While the corn crop in Illinois is being stored in Illinois farms this year, farmers are not yet fully satisfied with the quality of the crop. The main reason being the small amount of fertilizer used, especially in the corn belt of the College of Agriculture, University of Illinois.

In spite of the fact that only 100 bushels of corn are produced per acre in the best part of the corn belt, Illinois will still harvest a large amount of corn next year. The yield per acre will be about 100 bushels. However, the quality of the crop will be lower than in previous years.

With most of the corn being stored in Illinois farms this year, the quality of the plants remaining in the field, most of which are now being stored for use as silage. However, the quality of the silage will be lower than in previous years. At the same time, the quality of the silage will be lower than in previous years. It is risky, therefore, to use silage as a feed for livestock.

The best way to increase the yield of corn is to take care of the soil. This can be done by using a local fertilizer which is sufficient for the soil. The fertilizer should be applied in a fruit jar and the fertilizer should be applied to the soil in the corn belt.

Another way to increase the yield of corn is to use a local fertilizer which is sufficient for the soil. The fertilizer should be applied in a fruit jar and the fertilizer should be applied to the soil in the corn belt.

There are many ways to increase the yield of corn. One way is to use a local fertilizer which is sufficient for the soil. The fertilizer should be applied in a fruit jar and the fertilizer should be applied to the soil in the corn belt.

Another way to increase the yield of corn is to use a local fertilizer which is sufficient for the soil. The fertilizer should be applied in a fruit jar and the fertilizer should be applied to the soil in the corn belt. It is risky, therefore, to use silage as a feed for livestock.

Water in the Corn Belt as a Fertilizer for Corn

It is well known that the yield of corn is increased by the use of fertilizer. However, in Illinois, the yield of corn is not increased by the use of fertilizer. The reason for this is that the soil in Illinois is not fertile enough to support a large crop of corn.

However, if this is to give the best results, it must be applied with the right kind of manure. The manure should be applied in a fruit jar and the fertilizer should be applied to the soil in the corn belt. It is risky, therefore, to use silage as a feed for livestock.

There are many ways to increase the yield of corn. One way is to use a local fertilizer which is sufficient for the soil. The fertilizer should be applied in a fruit jar and the fertilizer should be applied to the soil in the corn belt. It is risky, therefore, to use silage as a feed for livestock.

## Illinois Feeds, Cattle, and Poultry for Soybean Crop

Illinois' soybean crop, which will furnish a good market for some of the state's surplus corn, may be well fed if the beans are used in the oil meal form, said W. H. All, poultry extension specialist at the College of Agriculture, University of Illinois. Soybean meal is a satisfactory protein supplement for the adult ration if the diet also contains sufficient mineral, he added.

For growing chicks, a ration of 1/2 lb. of meal, 1/2 lb. of corn with sufficient minerals of the right kind, 1/2 lb. of alfalfa hay or alfalfa meal, somewhat better than timothy, 1/2 lb. of clover hay or alfalfa, and now with as good as dry milk products.

For laying hens, 1/2 lb. of meal, and such an oil meal must be supplemented with calcium phosphate, and iodine. The minerals need for calcium, phosphorus, sodium, and iodine. The best source of the latter is a mineral mixture containing 2 percent barium iodide, 1 percent potassium iodide, and 1 percent salt.

The following is a formula for growing chicks: 1/2 lb. of meal, 1/2 lb. of yellow corn, 10 pounds wheat bran, 100 pounds ground alfalfa, 1/2 lb. of alfalfa hay, 1/2 lb. of soybean oil meal, 40 pounds alfalfa leaf meal, 2 pounds of calcium phosphate, 1/2 lb. of sodium arsenite, 1/2 lb. of sodium arsenite, and 5 pounds of salt. The above ration is a good one for corn and wheat and alfalfa and oats.

Whole soybeans are not very satisfactory, since they contain a large amount of oil which is difficult to digest. Because of this high fat content, they are not so good for use in the winter weather. The value of whole soybeans is about 1/2 that of commercial soybean oil meal. Another reason why whole soybeans form a large part of the ration is that ill-fed birds are more likely to be accustomed to a large amount of feed.

## They Do Not Have Problem With Art. College Graduates

Employment is not a problem in the ranks of the 12 graduates in agriculture who recently went out from the College of Agriculture, University of Illinois, last June, according to a letter published by Assistant Dean E. R. Anderson. More than 90 percent of those who have replied to his inquiry have jobs either in farming, a classroom, or the office, and the only ones still unemployed are nine graduates in home economics. To date, replies have been received from 98 of the 120 graduates. Since leaving school the graduates have been scattered to a dozen different states and Argentina, West Africa, to start their careers.

Opportunities for men and women trained in agriculture and home economics are indicated by the fact that the remainder of the graduates are engaged in various kinds of work. Some of the home economics graduates, Miss Ruth E. Vogel, formerly of Chicago, is clerking and modeling in a Chicago department store, while the range of work in which the agricultural graduates are engaged includes re-settlement, soil conservation, milk marketing, farm management, farmer organization and farm work.

General Features of the 1914-15 Season for Poultry in Illinois

General poultry management conditions in Illinois, as reported by the popular press, have been very favorable, and are reported by J. H. Aldrich, Extension Specialist for the U. S. Department of Agriculture, University of Illinois.

Anderson, who has been in the poultry business for a number of years, says that the year has been a very profitable one for the poultry raiser in Illinois. He says that more than a year ago he sold his first pair of chickens to a neighbor. He has since then raised chickens for sale in his own house. He says that he has never had a pair of chickens that were so profitable as the pair of this year. He says that he has never had a pair of chickens that were so profitable as the pair of this year. Protection Of Egg Injures Avoided By Early Plowing

Chemical applications and as in Illinois the fall and winter plowing in better shape for next year but also will be good protection against multiplication of insect and disease damage which occurred in some parts of the state this summer, according to E. L. Weaver, vegetable pathologist and entomologist of the College of Agriculture, University of Illinois.

Harold trustees, such as the, the beetles, the squash beetle and squash beetle are among the most common pests which caused the most damage at summer's degradation during the summer if left a bare field in which they had been allowed this fall. While the beetles are not as numerous as they were some years ago, they were prevalent in some sections of the state, and W. F. Flint, field entomologist for the college and the Illinois State Natural History Survey.

The learned that a major part of winter management is the protection of potato beetles against winter injury in the ground, while Mexican bean beetle hibernates under trees. Fall plowing will help to destroy the insects by the drying effects of the cold and the wind and the sun.

Any method of plowing which will turn the ground will destroy the insects for the fall beetle and the squash beetle. Plowing or plowing under the refuse will likely destroy the insects by the drying effects of the cold and the sun. It is just as effective as the method of plowing to prevent it, if done.

Plowing and plowing the beetles. Plowing will destroy the insects, and it is only the most common and the most common. Plowing will destroy the insects in other places where plowing is difficult or impossible. Plowing under the fall plowing under the ground, the insects are killed.

When the ground is plowed, it is a good idea to plow under the ground with the dead, plowing the ground under the ground. If the ground is plowed under the ground, the ground will be plowed under the ground.

15-

Frost Lays Out How Still Hold A How at Of Soil

Most of the land in the state is in a green, immature stage by early October. Frost will be a serious problem in the state and will be a serious problem in the state. Frost will be a serious problem in the state and will be a serious problem in the state.

Future growers start a thing like a seed, however, it will be a serious problem in the state and will be a serious problem in the state. Future growers start a thing like a seed, however, it will be a serious problem in the state and will be a serious problem in the state.

A more exact test is to plow the ground under the ground. Plowing will destroy the insects in other places where plowing is difficult or impossible. Plowing under the fall plowing under the ground, the insects are killed.

## First Month of Rural Electrification Aid To IFA Activities

Approximately 15,000 miles of rural electric power lines carrying voltage from which farm homes can be served have been installed for the first time by the agricultural engineering department and college of agriculture, University of Illinois as the aid to general interurban and rural power lines under the Rural Electrification Administration.

In addition to the numerous information on rural electrification available also is available from the report, "Rural Electrification," by E. W. Johnson, 1934. This information includes data on rural electrification, types of lines used, costs of operating, rate, and kind of equipment used in rural farm homes.

Showing a rapid increase in rural power lines in the state, the report offers many means of determining which areas are being served and those which are in need of rural power lines. The data presented in drawing the map was secured by the agricultural engineering department in the power companies in the state. Copies of the map may be obtained at a small charge to cover the cost of preparation.

Funds obtained through the year's operation of an experimental line running out of Urbana have given the college considerable aid in the realization of the electrified farm. The college of agriculture was the first to purchase a line and to have loans offered by the REA.

In connection with IFA activities in Illinois, the technical staff of the Illinois Commerce Commission is studying a new regulation which will set a new standard and will cut down on existing rural lines, according to the reports. Several quality companies are cooperating to make it possible for farmers to obtain electrical service. Since January 1, 1935, the college of agriculture has installed 138 miles of rural power lines on private farms. This includes 111 miles of lines in progress for the same line. The college is also participating in the construction of rural power lines.

## Rosie Prescient About Swine In Illinois This Fall

This was the case for this year, and very recently for the year 1934. In the Tiger and very many other swine and hogs, and infected with swine fever disease, it is reported by Prof. Fuller, head of the swine extension service at the College of Agriculture, University of Illinois. The swine fever disease is a commercial illness of swine and is a very serious disease of swine and is a very dangerous disease.

Pigs will have not been well this year, and it is dangerous to keep them cleaned of their infection, and it is dangerous to keep them from being infected, Fuller explained. The swine fever disease is a very serious disease. Any swine that is infected with either vesicular or erythematous disease should be killed and the carcasses buried. Pigs that are infected with either disease should be removed from the herd and the infected carcasses should be buried. Infected and any help spread the disease. The swine fever disease is a very serious disease.

Heredity Shown To Play Role in Animal Disease Fight

It has now been established that heredity plays an important role in resistance and susceptibility to at least one animal malady, pullorum disease, or bacillary white diarrhea of poultry, according to a new bulletin, "Inheritance of Resistance to Typhoid Infection in Animals," just published by the experiment station of the College of Agriculture, University of Illinois.

Following 10 years' experiments involving more than 29,000 chickens, the bulletin was written by Elmer Roberts, chief in animal genetics, and L. E. Card, chief in poultry husbandry. Pullorum disease was chosen for the study because it lends itself readily to the laboratory methods necessary in such an experiment.

During the 10-year experiment selection was effective in producing strains of fowls which were more resistant to pullorum infection than was the unselected stock. The success in breeding up resistance to bacillary white diarrhea indicates the possibility of developing strains of poultry or other farm animals which are resistant to certain diseases. Thus this genetic method would become an important aid to the other general methods, prevention and cure, in combating disease. However, the work has not progressed to the point where resistant strains of poultry and other farm animals are available for breeding purposes, the bulletin points out.

The experimental results were especially promising, since the selected birds were consistent in maintaining resistance to the disease through successive generations. A susceptible male mated to a susceptible female produced chicks much more susceptible to the disease than were chicks from the same susceptible male mated to a resistant female. No significant difference was found between progeny of susceptible and resistant females mated to the same resistant male. Nor was there any indication of acquired immunity among the birds, since the progeny of infected hens showed no greater resistance to the disease than did the progeny of noninfected hens.

Turkey Prospects Bright For Finished, Quality Birds

Turkey market prospects are favorable for Illinois growers who are careful to raise only birds of top finish during the approaching holidays, said H. H. Alp, poultry extension specialist at the College of Agriculture, University of Illinois. Large numbers of turkeys being raised in many of the main producing areas outside the state give promise of a reasonably high holiday price.

However, this does not mean that turkeys with poor finish or other inferior qualities can be expected to bring good prices, Alp said. While the decrease in production is reported by the U.S.D.A. as approximately 13 per cent below 1934, this is considered sufficient to put a premium on inferior birds. On the other hand this decrease together with improved business conditions may bring turkey raisers a better holiday season for quality stock than they have enjoyed for several years, he added.

Culling out turkeys of poor finish and marketing only top quality specimens during the Thanksgiving season, growers will have at least three weeks in which to bring up birds to top finish for the Christmas and New Year's season. Thus they will be able to get good prices for a large percentage of the turkeys sold.

Decreases in production have been principally among farm flocks rather than among the large commercial flocks, according to the U.S.D.A. report, which states that 15 per cent fewer farmers in the south Atlantic and far western states reported turkeys, while the decrease was nearly 10 per cent in the other sections.

The heaviest reductions in numbers of turkeys are reported from the main producing states such as Texas and North Dakota. Increases are reported for Minnesota, Oklahoma, Pennsylvania, northern New England and several of the southeastern states. Illinois production is above last year, Alp believes.

-M-

Tests of a Hybrid Corn (Zea mays) for Hybrid Vigor

Hybrid corn varieties, which are so valuable for their superior grain producing qualities, have now shown that they may also be superior hybrid varieties for silage purposes, according to results of tests made by W. B. Hayes, associate chief in dairy cattle feeding, at the College of Agriculture, University of Illinois.

The hybrids contained a higher proportion of grain, had greater resistance and gave slightly higher yields of dry matter in the dry matter of the silage. Sixteen hybrid varieties used in the trials were, in the whole, superior to Station Yellow Dent, a high yielding strain of Reid's Yellow Dent, used in the control plots. Both hybrids and the open-pollinated variety made large yields of silage, ranging from 12 to 13 tons an acre. The tests were conducted by the dairy dictionary and agronomy departments of the College with the cooperation of the U. S. D. A.

One of the most significant advantages of the hybrids was their resistance to logging, decay and mold. Sixty per cent of the hybrids were stored in great quantities from September 15 until January 15, 1937, 84 per cent of the Station Yellow Dent variety.

Another advantage of the hybrids was their higher proportion of grain. Fifty-two per cent of the total dry matter of the hybrids contained dry matter compared to the same amount of Station Yellow Dent which contained only 47 per cent of the total dry matter. The hybrid varieties also produced slightly less dry matter to the acre, but not enough to be of particular significance, Hayes states.

Since the experiments have only been carried through one season, the results should not be taken as conclusive evidence of the superiority of hybrid varieties for silage, but should be viewed as preliminary research. However, the trials indicate that hybrids may be used very satisfactorily for silage production as well as for grain production.

Injury to Sheep from Ticks and Isomacrus

The first cases of sheep injury reported during Illinois cattle this fall were the first serious cases and were by this report on the part of Dr. E. Flint, chief entomologist for the College of Agriculture, University of Illinois and the Illinois State Natural History Survey. The incident indicates that the insect may be not a serious pest and is not a tick, but a mite on sheep and other animals.

Sheep were never reported to be infested with Isomacrus in Illinois until this fall when they killed all of the animals on the west central portion of the state. It is believed that heavy infestation was brought in from the south and Illinois feeders.

The fly attacks and irritates the animal, but does not cause a disease or death of cattle, sheep and goats. It is a pest, however, because it is a blood sucker. The eggs are laid in open wounds and may be hatched from the animal's wounds, the animal's skin, dehorning, branding and other machinery. The fly is a nuisance from the eggs and should be removed from wounds with a wash of water saturated with kerosene. The fly should be removed mechanically, as there is danger of poisoning the animal if the fly is crushed. Wounds should be coated thoroughly with iodine to kill the insect and prevent further infection. Wounds should be treated with antiseptics.

Other means of control include burning and the use of insecticides. In June and by avoiding landings on other animals. Larvae of the insect are most prevalent. All cotton wads of any kind should be removed from the animal's body. Open wounds should be treated with iodine to prevent infection.

## Terracing Record So Far New High In Erosion Control

Record advances are being made this year against erosion in Illinois! A million acres of rolling cultivated land with the building of more terraces than in any previous year in the state's history, it is reported by R. C. Hay, agricultural engineering extension specialist of the College of Agriculture, University of Illinois.

Activities are at their height this fall, with forces of the extension service, U. S. Soil Conservation Service and CCC camps cooperating with farmers to get terraces built and outlets finished before winter. Much of the work is being carried on through the various county soil conservation associations which have been set up recently in many counties of the state.

In 11 counties terracing machines either have been purchased or leased by the associations and are being operated by the associations in cooperation with CCC camps and the conservation service. Taylor, Jersey and White counties are using large 14-foot blade terraces. Eight-foot blade terracers have been purchased in Taylor and Marshall-Fulton counties, while the new wheel-type machine is in operation in Mason, Adams, Sangamon, Randolph, Jackson and Williamson counties, Hay reported.

These machines, either owned or leased by the county associations, are being operated by tractor camps. Some of the associations can their own tractors, while others have contracted with local dealers or farmers to furnish them. Funds at whose places the terraces are built cover the cost of an hourly rate calculated to meet operating expenses and the approximate cost of the machine.

In addition to the outfits operated by county associations, many privately and publicly owned machines are being used. These range from old fashioned terracing machines suitable for horse or man tractor power up to large road graders.

Terraces are being laid out and checked by engineers from the conservation camps and outlets are being constructed by CCC men. Assistance has been given to all of these projects by the agricultural engineering department of the college.

-1-

## Music And Drama Features Drawing Rigger Entry List

The largest turnout of church talent in the seven year history of the contest already has started preparations for the annual state music and drama contest to be held during Farm and Home Week, January 11 to 13, at the College of Agriculture, University of Illinois, according to D. L. Lindstrom, general secretary and specialist at the college.

Fifty-six counties are expected to compete to this year's contest, the same as last year. The state has been divided into 14 districts and each district will send a choir to reside in each of these districts. Choirs from the state of Illinois will be held in Taylor county and are being placed in Taylor county. Choirs from other states will be held in the remaining 47 counties expected to participate. Each of these types will have a chance to display and exhibit their talents.

New High Reached In Bang's Disease Control In State

A new high for accomplishments under the Bang's disease eradication work in Illinois has been reached by the Coles County Dairy Herd Improvement Association with 100 per cent of the member herds entirely free from the disease, according to a report received by C. S. Rhode, dairy specialist at the College of Agriculture, University of Illinois, from Marvin Fairchild, tester for the association.

This is the first dairy herd improvement association in Illinois to have all its herds free of Bang's disease, Rhode believes. The accomplishment marks one of the first big milestones on the eradication program that was started some 14 years ago by the animal pathology and hygiene division of the college.

During those years approximately 25,000 cows, 300 swine and 214 goats have been tested under the state-wide project which the college is carrying on to combat the disease. The malady not only has cost farmers of the state thousands of dollars but also has endangered public health. Humans may contract undulant fever by using products from Bang's infected herds, said Dr. Robert Graham, chief in animal pathology and hygiene.

Since the project was started, 111 of the 1,106 herds that have been tested have been freed of the disease. In the remaining herds testing and control measures are rapidly cutting down the losses. Conservative estimates are that Illinois farmers have saved \$45,000 through tests.

In 1934 the Federal government launched a more intensive eradication campaign which, up to June 30, 1935, has been responsible for eliminating 11,714 reactors from Illinois herds. Under this plan farmers may sign up to have their herds tested and all reactors are removed. Farmers receive indemnities under the federal plan for all reacting cattle.

-3-

Home Improving Picks Up With Improvement In Income

Substantial improvement registered in farm income during 1935 has been one of the main factors in the increased interest of farm women in kitchen improvement, according to Miss Gladys J. Ward, home management extension specialist at the College of Agriculture, University of Illinois. Nearly 400 farm women have been reached during the series of "kitchen clinics" conducted in nine counties this year, Miss Ward estimated. In all of these clinics the idea of making the kitchen more convenient without a large cash expenditure has met with enthusiasm. Counties in which clinics have been held are Adams, McDonough, DuPage, McLean, Coles, Warren, Mason, Iroquois and Knox.

In many cases a few home made shelves together with a rearrangement of the kitchen furniture and equipment was all that was necessary to make the room a convenient, cheerful place. One Mason county homemaker reported that her kitchen has been greatly improved by eight changes which cost a total of 27 cents plus the time spent by herself and husband. The changes included moving the range, moving the sink, building a drain board for the sink, adding a built-in cabinet, putting a partition in the cupboard, placing a silver drawer under the sink, adding a soap rack above the sink and equipping an old pantry for wrap storage.

Water systems were among the most needed of the home improvements involving a greater cash outlay than the minor changes, Miss Ward said. Only about 17 per cent of the rural homes of the state have running water, according to a Federal Housing Administration survey conducted during 1934. While the cost of a complete system involves considerable expense over a short period of time, the installation of the system by units is one method of spreading the cost over a longer period.

-4-

### Home Accounts Are Safe Guide In Increased Spending

Home accounts being kept by more than 639 Illinois farm and small-town homemakers are furnishing at least a partial guide to many homemakers who are wondering how their increasing incomes should be spent for food and other family needs. Ruth B. Freeman, home accounts extension specialist at the College of Agriculture, University of Illinois.

The average of \$417,000,000 in 1935 farm income over that of 1934, as reported by the Bureau of agricultural economics, has lightened the job of maintaining a high standard of living, but also has brought on the risk of unplanned spending.

More than 600 families have kept accounts for three or more years, and these accounts furnish valuable budget planning data both for the account keepers and for families of similar size. Many women who have wondered whether they were spending too much of the family income for food or economizing to the point of being unwell now are using these "average family" records for comparisons. The 1934 records show that the average family in the \$500 to \$999 a year income class expended approximately \$320, or 39 per cent, of the total income for food. In the \$1,000 to \$1,499 class, a smaller percentage of the total income went for food, and in the \$1,500 to \$1,999 class, less was spent for food, Mrs. Freeman said. Only 22 per cent of the families were included among account keepers having annual incomes of \$2,500 or more. The 1935 records are not yet available.

One benefit brought out by home accounts is that many farmers and small-town homemakers reduced cash expenditures for food by producing garden, dairy and poultry products. Among some of the low-income groups as much as \$209 worth of the food used in 1934 was produced at home. However, families in the higher income brackets also reduced cash food expenditures by raising food at home. The figures as these and many others derived from summaries of home accounts records are valuable data on meal planning as well as the budgeting of clothing and other family expenditures.

### Less Expensive Dairy Feeds Help Raise Net Incomes

More than one Illinois farmer is making the most of the improved prices for feed by adopting economical feeding methods, according to reports reaching G. B. Smith, dairy husbandry extension specialist at the College of Agriculture, University of Illinois. Savings made through more economical feeding are only one of the reasons why more than 1,100 farmers who are members of dairy herd improvement associations are increasing their returns, he said.

Substitution of home-grown grains for more expensive protein feeds together with replacement of part of the corn by oats are two ways by which Illinois dairymen are making it possible to cut feed costs without lowering their herd production averages. One member of the McLean county No. 1 association increased his monthly net income from 17 cows by \$10.88 with a less expensive ration. Oats replaced a part of the corn in the ration, thus reducing the cost of feeding approximately 24 cents a hundred pounds. His herd also produced 34 more pounds of butterfat a month on the cheaper feed.

A member of the Vermilion-Edgar county association used a ration composed of oats and distiller's grain instead of corn and a high protein supplement previously used and was able to cut feed costs by nine cents a hundred pounds, although the protein content was the same. The cheaper ration reduced the feed cost of butterfat by five cents a pound and the feed cost of milk by 14 cents a hundred pounds,

## Conferences For Young Folks Next In State Program

Latest among the rural young peoples' organization developments in Illinois is a series of conferences, the first of which is scheduled for December 9 to 12 inclusive at the College of Agriculture, University of Illinois, according to announcements by Miss Cleo Fitzsimmons and G. S. Randall, junior club extension specialists in charge of young peoples' activities throughout the state.

Special instructions in play presentation, discussion leadership and program planning will be given to delegates during these conferences which are being planned to give each delegate an opportunity to take an active part in the program. Dates and locations for the remainder of the series will be announced just as soon as they have been definitely set, Randall said.

This series is only one of the late developments with regard to the rural young peoples' groups which are being organized and sponsored by the extension service at the college to give farm boys and girls between the 4-H club and adult age a greater part in the community's activities. Another late development is the special exhibit of young peoples' hobbies which is being planned for Farm and Home Week, January 13 to 17. This exhibit will be set up because of increasing demands by local organization planning committees for such information.

Along with these special activities, interest in organization continues to move upward in the state. Initial steps toward setting up groups were taken in DeWitt, McLean and Montgomery counties during October. Others already organized are planning their winter programs with drama as a favored project. Macoupin, Shelby, Scott, Pike, Williamson and Edwards county organizations are making plans to produce plays this fall and winter. Other groups have or are planning to take trips to historic spots of Illinois as a part of the "Know Illinois" project.

The Edgar county young men's forum which has been conducting discussions during the past three years considered two topics, "Illinois Sales Tax from the Farmer's Standpoint," and, "The Illinois Property Tax Law from the Farmer's Standpoint," during their last discussion series.

Many young peoples' groups plan to attend the agricultural economics schools where these sessions are being conducted in their counties by the agricultural economics department of the college.

-M-

## Greater Interest Is Being Shown In Farm Discussions

Increasing interest of Illinois farm people in discussions dealing with the problems of agriculture is indicated by the fact that 10 county teams plan to enter the state discussion team tourney this year as compared to four teams last year, according to D. E. Lindstrom, rural sociology extension specialist at the College of Agriculture, University of Illinois.

This year's tourney, second of its kind to be held in Illinois, will take place during annual Farm and Home Week, January 13 to 17. The topic for discussion will be, "How Should Agriculture Adjust Its Production."

-M-

Family Of Six Can Use An Orchard Of 12 Fruit Trees

It takes about 12 fruit trees and 12 small fruit plants to supply the average family of six with the fruit it needs, according to estimates prepared by V. W. Keller, horticultural extension specialist of the College of Agriculture, University of Illinois. Such a planting would produce, on the average, approximately 20 bushels of tree fruit, 250 pounds of grapes and 10 quarts of small fruits.

The estimates were prepared in reply to the many Illinois farmers who are planning to start small home orchards to supply fruit for their own families. Liberal allowance was made in the figures for fruit for canning.

The number of trees recommended for the average family of six plus occasional hired help, includes six apple trees, three pear trees, two peach trees, three plum trees, two cherry trees, one or two sweet cherry trees. A separate variety should be chosen for each tree so that the six crops will ripen through the fruit season, Keller explained.

In the small orchard also the estimated number of plants includes 2 grape vines, 250 strawberry plants, 30 to 40 raspberry bushes, 20 wild raspberry plants, 25 blackberry plants, 10 to 15 cherry tomato and 10 sweet corn plants. While the number of trees and small fruit plants is small, better and larger crops usually are produced from relatively small orchards because of the better care these orchards receive. The large orchards are more neglected, Keller said.

This selection will need to be varied according to local soil and climatic conditions as well as individual preference. Some varieties of apples, peaches, for example, are found only in the northern half of the state. Sweet cherries grow best in the north, especially in the northern part of the state. The prospective home orchardist would consider growing suitable plants in place of fruit making final choices as to kinds of fruit to be grown.

How To Use Well Built To Protect Wealth Of Family

Health and safety of Illinois families during the coming winter months may be protected to a great extent by preparation and maintenance in the home before cold weather arrives, Richard W. A. Foster, rural specialist at the College of Agriculture, University of Illinois.

One of the greatest dangers which can be eliminated as provision is made to have kindling ready for starting fires during fires. There is often a temptation to create the fire place by burning newspapers and freshly-sailed tires. The all too frequent news of people being burned to death from this cause indicates that it will be much safer to have a good supply of kindling near the stove and the hearth. Supplied in the form of well packed coils or chips which may be placed on the fire with a risk, Foster said.

Another detail which, if taken care of properly, will do much to prevent unnecessary calls is that of repairing and caulking doors to keep out cold drafts. A rattling window may be repaired by the resetting of the sash or the addition of seals made of built-up paper rickens or felt strips. Cracks which permit cold drafts to enter the room under the base can be repaired in the same way. Loose fitting doors can be repaired by the use of brass or other metal strips for which can be obtained at a nominal cost.

Concerning the cracks between the basement wall and the sill as well as replacement of broken casement windows will go a long way toward insuring the all-around and eliminating the necessity of costly calls to repair and and and and and and small children in the family.

49 State Champions Named From 4-H Club Membership

Forty-nine 4-H club state champions and 43 state honor roll members have been chosen for their outstanding work from among 14,000 club members engaged in agricultural projects in Illinois during 1938, according to an announcement just made by E. I. Filcham, junior club extension specialist at the College of Agriculture, University of Illinois. The championships represented 28 counties and the honor roll 49.

To win a state championship, club members had to make a score of 80 or more in some chosen better farming project supervised by the extension service of the agricultural college and their county farm advisers. Honor roll winners were required to score between 70 and 80.

Fulton county clubs topped the list with seven of the 49 championships and five members listed in the honor roll. Sangamon county was second with five state champions and two honor roll members, while Lake county placed third with four champions.

State champions in agricultural projects include Edwin Allen, colt, and Opal Ward, horse and ride beautification, Kankakee county; Milton Bell, beef, Champaign; Lewis Benckhardt, beef, LaSalle; D. ne Brett, pig, and Kenneth Ferill, corn, Morgan; Herman Brown, pig; Alice Buecker, poultry; Alvin Davis, sheep; Mary Richardson, horse grounds beautification, and Max Sargent, pig, all from Sangamon; William Brown, dairy, Winnebago; Paul Engel, colt, Washington; Fred Francis, corn, beef, Will. Webster Gehring, Jr., pig, King; William E. Greenberg, corn, and Willie Hodden, beef, Morgan; William Hamilton, beef, and Robert Harris, corn, McDonough; Henry Hartman, corn, McHenry; Earl Kane, pig, Stark; L. Ke; Charles Lamb, pig, Edgar; Keith Lynch, poultry, Marion; Donald O. May, poultry, and William D. Masters, sheep, Fulton; Donald Mosher, pig, DeKalb; Earl Outrey, pig, and James Potter, pig, Florida; Sam Ridlen, poultry, Williamson; Dean Sims, sheep, Adams; and Robert Stetsen, pig, Bureau.

State stock champions are Gilbert P. Everett and J. Harrison Buckingham, demonstration team, Tazewell; Tom and Frank, Kenneth Voorhees and Maurice Wilson, corn judging team, and Ralph Foulk, Belle Smith and Charles Turner, poultry judging team, Fulton; Delbert Gardner, dairy judging, Warren; Belle Johnson, poultry judging, Mercer; Earl Kane, Jr., Harry Lehman and Herman Mohrer, dairy judging team, Lake; James Padgett, livestock judging, Adams, and Bert Phillips, James Smith and Wayne Wilson, livestock judging team, Marshall-Putnam.

Members of the honor roll are Frederick W. Boetel, Jr., DePage county; James Carline, Jefferson; George Bertelsen, Warren; John Cameron and Norman Smith, Marshall-Putnam; Jeanne Coutes, Bureau; Bernard Deakin, John Ewan, Garold Kopple, Ernest Krider and Kenneth Voorhees, Fulton; Homer F. Dodd and William E. Perish, Edgar; Robert Dunlap, Champaign; Burdell Gardner, Joan Hahn and Joe Hully, Livingston; Ira Hamer, John Owen Kuhn and Ruth Stetchel, LaSalle; Jim Henderson, Tazewell; Eugene Hidsen, Williamson; Kenneth Frager, Massac; Edna and Miller, Vermilion; Dean Miller, Henderson; Daniel E. Moeller, LaSalle; Nelson Thomas, John Roesch and Ruth Toben, Ford; L. Vern Nichols, Washington; John Paarlberg and Kenneth Paarlberg, Cook; Francis C. Potts and Robert Summers, Sangamon; Axel Rosmussen, McHenry; Myrtle Rutledge, DeWitt; Fred Spickler, Winnebago; Lorette Stauffenberg, Will; Edwin Thornton, Mercer; James L. Vant, Stark; Harold Winter, McDonough and Myrtle Woodward, Bond.

Basement Party Fills Place Once Held By Hushing Bees

While rural young folks of Illinois do not have the barn dances, hushing bees and other entertainments enjoyed by their fathers and mothers, they do have modern homes with basements where they can set up recreation rooms for parties, dances and other winter get-togethers, according to W. A. Foster, rural architect at the College of Agriculture, University of Illinois.

A well-built basement can be transformed from a dusty catch-all to an attractive and comfortable recreation room at a relatively small cost. Such a room will be ideal for organized meetings, parties or those informal get-togethers where young people of the neighborhood spend pleasant winter evenings playing games and enjoying popcorn, apples and other cold weather specials, Foster said.

If the walls are of concrete they may be painted or plastered. Stone or brick walls also can be painted or plastered, although a more attractive finish can be had if they are lined with knotty pine boards. This finish also can be applied to concrete walls if desired. Wall plaster should be made with a cement base.

There are a variety of ways of finishing the floor after it has been troweled smooth. It may be covered with homemade rugs or with a plain, heavy linoleum. It also may be painted. The painted or linoleum-covered floor makes an excellent surface for dancing or games.

Where sufficient money is possible, a fireplace adds a great deal to the basement recreation room, since it imparts a cheery warmth and serves as a focal point for arrangement. Although a basement fireplace is more easily installed when the house is being built, it can be put in later, especially if there is a fireplace in the room above.

A basement recreation room may be constructed at a cost ranging from a few dollars to \$100 or more but, regardless of the cost, it will be an investment in home supervised recreation, youth, health and friends--assets which are not measured in dollars, Foster declared.

Wheat Land May Need Reseeding Because Of Hessian Fly

Because of continued warm weather far into the fall this year, a late brood of Hessian fly is doing considerable damage to wheat in many sections and may necessitate the reseeded of some fields next spring, according to W. P. Flint, chief entomologist for the College of Agriculture, University of Illinois, and the Illinois Natural History Survey.

The fly damage was brought about by the emergence of a brood at least a month after the normal date of seeding for highest yield, Flint said. With the mild fall weather, eggs laid at that time developed, causing the present Hessian fly infestation. Usually eggs laid after November 1 will not develop sufficiently to cause serious damage.

On strong ground much of the wheat will recover from the damage and send up tillers which will produce a crop next summer. However, the infested fields should be watched and, if the wheat becomes seriously damaged, it may be necessary to reseed the land next spring.

Since there is every indication that the spring brood of Hessian fly will be plentiful, fields damaged by this fall's infestation probably should be reseeded to a fly-resistant crop such as oats, Flint said. Aside from wheat and barley, rye is the only other grain subject to fly damage.

Hard freezes which may be expected in most sections of Illinois from the latter part of November on will have no effect in ridding fields of Hessian fly before next spring. Consequently, this fall's infestation may be a forerunner of a heavy infestation when the 1936 crop season begins.

## Spirited Race On For Grain Honors At Illinois Show

Competition for the "corn king" title of Illinois, now held by C. J. Simmons, Rockton, is expected to be more spirited this year than for a number of seasons when the state's best corn growers come together next month during the annual Illinois Seed Grain and Utility Corn Show, according to J. C. Hackleman, crops extension specialist of the College of Agriculture, University of Illinois.

As in former years the show will be a feature of the annual Farm and Home Week to be held January 13 to 17 at the college.

Other title holders besides Simmons whose honors will be at stake in the various divisions of the show are C. E. Canterbury, Cantrall, soybeans; F. W. Wilson & Son, Edgewood, sweet clover seed; Russell D. Maurer, Carlock, red or mammoth clover; Keith McGuire, Tuscola, early oats; Keith Turner, Seymour, hard winter wheat; Clarence Kin, St. Francisville soft red winter wheat; Virgil Beckerman, Mt. Carmel, "corn prince," and George Shuman & Son, El Paso, 10-acre corn growing contest.

Stimulating interest in the show this year is a harvest of important crops that for the state as a whole is generally good. The combined acre yield of important crops is above the 10-year average. This year the show can draw on a crop of 84,588,000 bushels of corn as compared to the drought-riddled 1934 crop of 146,760,000 bushels. The state also has a record crop of almost 19 million bushels of high quality soybeans.

One indication of the large number of entries expected in this year's show is the fact that 17 growers have entered the 10-acre yield contest as compared with nine last year. For the show as a whole, the total number of entries is expected to be considerably larger than the 218 in the 1935 event.

Chief interest in the show is expected to center in the 10-ear classes for yellow and white corn, from which the new "corn king" and "corn prince" of the state will be picked. There will be 10-ear classes both for junior and adult exhibitors. Other classes will be provided for peck samples of shelled seed corn and for the various small grains.

Prices for the corn show winners will be presented at the annual banquet of the Illinois Crop Improvement Association on the evening of January 15.

Growers expecting to enter the competition may secure copies of the premium list by writing the college.

Addition of two more addresses completes the list of speakers for the general sessions of the week. Mrs. Emily Newell Blair, of the Consumers' Division, NRA, will speak Thursday, January 16, on, "The Work of the Consumers' Council," and Dean Chris L. Christensen, of the College of Agriculture, University of Wisconsin, Madison, Friday, January 17, on, "The Agricultural-Industrial Balance in Our Economic Life."

Holiday Expenses Budget Is Reduced by Several Percent

The Extension Committee on the basis of a study made by the Extension Agents in Illinois has reported that the average family budget for the Christmas season is \$100.00. This is a decrease of 10% from the \$110.00 reported last year. The Extension Agents reported that the average family budget for the Christmas season is \$100.00. This is a decrease of 10% from the \$110.00 reported last year. The Extension Agents reported that the average family budget for the Christmas season is \$100.00. This is a decrease of 10% from the \$110.00 reported last year.

In some cases insurance companies will be willing to allow the insured to pay the premium for the year ending in December instead of January. This is a very desirable arrangement for the insured as it allows him to pay the premium in advance of the time to lighten the Christmas load. It is also desirable, necessary to let the insured know that the opening of the Christmas season has not been a heavy one for the insured and that the opening of the Christmas season has not been a heavy one for the insured.

However, the Extension Agents reported that the average family budget for the Christmas season is \$100.00. This is a decrease of 10% from the \$110.00 reported last year. The Extension Agents reported that the average family budget for the Christmas season is \$100.00. This is a decrease of 10% from the \$110.00 reported last year.

With this in mind, the Extension Agents reported that the average family budget for the Christmas season is \$100.00. This is a decrease of 10% from the \$110.00 reported last year. The Extension Agents reported that the average family budget for the Christmas season is \$100.00. This is a decrease of 10% from the \$110.00 reported last year.

The Girls' Bureau Plans To Have a Lively Year

Twenty-two thousand girls of high school age are reported to be in the girls' clubs in Illinois. This is a record for the girls' clubs in Illinois. The girls' clubs in Illinois are reported to be in the girls' clubs in Illinois. The girls' clubs in Illinois are reported to be in the girls' clubs in Illinois.

Furthermore, the girls' clubs in Illinois are reported to be in the girls' clubs in Illinois. The girls' clubs in Illinois are reported to be in the girls' clubs in Illinois. The girls' clubs in Illinois are reported to be in the girls' clubs in Illinois.

A third line of endeavor was that of home furnishings and room improvements. Girls are busy in projects of this kind, and it is reported that the girls' clubs in Illinois are reported to be in the girls' clubs in Illinois.

There is a great deal of interest in the girls' clubs in Illinois. The girls' clubs in Illinois are reported to be in the girls' clubs in Illinois. The girls' clubs in Illinois are reported to be in the girls' clubs in Illinois.

Margie Lee, of Lake county, has been able to guard her health more carefully through the principles learned in the health project, she reports.

The Problem of Farm Productive Land

People over plant their front lawns, or grow other crops, and refuse to grow a bush of any vegetables as they please, and give them no room to grow without any restrictions or penalties which are imposed on the soil to which they are put. A good object of agriculture is to grow crops which are profitable and which will sell for a price which will give the farmer a profit.

In addition to all this, farmers are often asked to grow crops for the benefit of their tax-free allotments. Without any penalties or restrictions on the soil, the situation is not. Most of the time, the farmer is asked to grow crops which are not profitable to distinguish between the methods of growing.

The other restrictions on the soil are the result of the fact that the farmer is asked to grow crops which are not profitable to distinguish between the methods of growing. The farmer is asked to grow crops which are not profitable to distinguish between the methods of growing.

People are often asked to grow crops for the benefit of their tax-free allotments. Without any penalties or restrictions on the soil, the situation is not. Most of the time, the farmer is asked to grow crops which are not profitable to distinguish between the methods of growing.

The only way to distinguish between the methods of growing is to grow crops which are not profitable to distinguish between the methods of growing. The farmer is asked to grow crops which are not profitable to distinguish between the methods of growing.

The only way to distinguish between the methods of growing is to grow crops which are not profitable to distinguish between the methods of growing. The farmer is asked to grow crops which are not profitable to distinguish between the methods of growing.

## Ten District Events Set For Next Year

Maximum interest in farm improvement and broad, ten district events will be held January 7 to 11 to select entries for the annual state fair and to inaugurate the district trials. The district trials will be held at the College of Agriculture, University of Illinois.

The district trials will be held in the women's contest, crop contests and other events. The district trials will be held in the state of Illinois, which will be held in the state of Illinois. The events of the thirty-ninth annual Farm and Home Week at the college.

There will be a contest which will have the largest turnout. The contest is the seven-year district trial. The contest will be held in the state of Illinois. The contest will be held in the state of Illinois.

Save Cattle Best Not Rushed Into Market This Season

Although there are more cattle on feed in Illinois this winter than last, it probably will pay farmers with plenty of home-grown corn to feed quality cattle long enough to get a prime finish before marketing them, said R. R. Snapp, associate chief in beef cattle husbandry at the College of Agriculture, University of Illinois.

On the other hand, the feeder who has poorer grade cattle and only a limited supply of corn but plenty of good clover hay and corn silage may find it to his advantage to put the cattle only in good butcher condition and sell them as short feeds rather than buy corn for a full feeding period.

The feeder who purchased his cattle between November 1 and 15 and who intends to market them before summer should have the cattle well on corn by the latter part of December. While early gains can very well be made from hay, stalk pastures, second growth or seedling clover and alfalfa remains, the animals may stop gaining or actually lose weight if they are not fed enough grain when cold weather sets in, Snapp said.

While there is no danger of beef cattle going off feed if put on full feed of corn too suddenly, the gradual change from hay and roughage to grain should be made in most cases before the first of the year.

This gradual change does not apply to choice, fleshy feeders that are to be put in prime condition in a relatively short period. Such cattle should be started on corn as soon as they reach the feed lot and then increased to full feed by the end of the second or third week.

Future market trends along one uncertain but indications are that this winter and spring's beef cattle markets will remain good provided heavy sales don't glut the market. Consequently, the feeder's profit depends largely upon his individual situation and supply and kinds of feed on hand, Snapp said.

Plenty Of Water Is Best Protection From Fire

An adequate supply of water is one of the best guarantees Illinois farmers can have against fire, which has destroyed numerous lives and thousands of dollars' worth of property already this winter, according to W. A. Foster, a real architect at the College of Agriculture, University of Illinois.

The hourly supply of water for an engine throwing a one-half inch stream may often mean the saving of a building. Since the engine of such dimensions will require about 50 gallons of water a minute, the supply should amount approximately to 100 barrels.

This is not an expensive supply to have on hand, Foster said. A cistern 10 feet in diameter and seven feet deep will hold this amount. A circular tank eight feet each way, or about the size of a ton of hay in a row, will hold approximately 100 barrels of water. A small dam in the spring run or in a convenient stream will impound enough water for fire fighting purposes. The pond formed by the dam not only will furnish a much-needed water supply but also will add to the beauty of the premises. It will serve as a center for landscaping and may even be used as a skating pond during the winter.

Even where road conditions or distance make it impossible for a small town fire department to answer rural calls, the water supply is a valuable protection, Foster declared. Plenty of water, a good supply and conveniently located tanks will enable neighbors to quench many a fire before it can had time to get a good start.

When considering building problems, it is well to make arrangements for the water supply and if possible install pressure water equipment.

How Seed Is - Will Help Agriculture in Illinois

Work done on the seed law introduced by the Illinois Legislature in Illinois during the past year has already started in Illinois, and the law is now being put into effect. It is a standard measure which will help to bring the seed law in Illinois in line with the seed law in other states of the Middle West. It is a measure which will help to bring the seed law in Illinois in line with the seed law in other states of the Middle West.

Seed corn will be made at least one percent more per bushel. Inspective seed applied can be tested readily by the use of the well known "rag doll" tester. This tester is made by the use of a standard bushel of seed corn and of the tester, the seed is put on their flat and rolling the two pieces together in a ball. The water in the seed is at a temperature of about 70 degrees.

Testing the seed corn will give the farmer an opportunity to secure additional seed. It is a measure which will help to bring the seed law in Illinois in line with the seed law in other states of the Middle West. It is a measure which will help to bring the seed law in Illinois in line with the seed law in other states of the Middle West.

While it is not yet known whether the seed law will be passed, it is believed that it will help to bring the seed law in Illinois in line with the seed law in other states of the Middle West. It is a measure which will help to bring the seed law in Illinois in line with the seed law in other states of the Middle West.

During the past year the Illinois Legislature has passed the law which will help to bring the seed law in Illinois in line with the seed law in other states of the Middle West. It is a measure which will help to bring the seed law in Illinois in line with the seed law in other states of the Middle West.

Illinois National Soil Conservation Bill Still Pending

By securing larger acreage devoted to the production of crops, 1937 Illinois farmers will be able to produce more crops. It is a measure which will help to bring the seed law in Illinois in line with the seed law in other states of the Middle West. It is a measure which will help to bring the seed law in Illinois in line with the seed law in other states of the Middle West.

The cost of the seed law is being paid by the farmer. Five Illinois farmers reported a average cost of \$1000 per acre in seed and that the cost of \$1000 is paid by the farmer. It is a measure which will help to bring the seed law in Illinois in line with the seed law in other states of the Middle West.

How Farmers Can Save \$1 A Bushel More

A present for a net level of retail prices, Illinois farmers are expected to save an average of \$19.00 per bushel of seed corn. It is a measure which will help to bring the seed law in Illinois in line with the seed law in other states of the Middle West.

This estimate is based on a report of the Illinois State Board of Agriculture from Urbana. At the present time the farmer is paid only \$1.10 for a bushel of seed corn and the cost of the seed is \$1.10. It is a measure which will help to bring the seed law in Illinois in line with the seed law in other states of the Middle West.
